

Salmon Stocks and Fisheries in England and Wales in 2015

SALMON STOCKS AND FISHERIES IN ENGLAND AND WALES, 2015

Preliminary assessment prepared for ICES, March 2016

Acknowledgement:

This report has been compiled jointly by staff from the Cefas Salmon and Freshwater Fisheries Team at Lowestoft and fisheries personnel from the Environment Agency and Natural Resources Wales. The monitoring and assessment of salmon stocks is funded by Defra and Welsh Government. All the participating organisations would like to extend their thanks and recognition to the various operational fisheries staff who have collected and compiled the data for this report. Thanks are also due to: the National River Flow Archive at the Centre for Ecology and Hydrology for providing river flow data; to the Game and Wildlife Conservation Trust for data relating to the River Frome; to the General Secretary of ICES for permission to cite the reports of the ICES Working Group on North Atlantic Salmon; to NASCO for permission to include their summary of regulatory measures for the high seas fisheries; and to Graphic Solutions (E.A.) Limited for preparation of the final report.

FOREWORD

Annual reports on the status of salmon stocks and fisheries in England and Wales have been produced since 1997. These reports present a preliminary assessment for the latest year to assist ICES in providing scientific advice to NASCO and to provide early feedback to fishery managers and anglers. The list of questions posed by NASCO to ICES for consideration in 2016 is provided at Annex 1 of this report.

For much of the period, the annual reports were prepared by the Centre for Environment, Fisheries and Aquaculture Science (Cefas) and the Environment Agency. However, from 1 April 2013, the functions of the Environment Agency in Wales transferred to a new body, Natural Resources Wales (Cyfoeth Naturiol Cymru) (NRW). This body is now responsible for salmon management and regulation in Wales. All three organisations have therefore contributed to production of the annual assessment report since 2013.

Until 2013, each annual assessment report was designed to stand alone, to avoid the need to refer to previous reports for background information. However, this resulted in much of the descriptive text being very similar year-on-year. From 2014, therefore, and in the interest of streamlining procedures, the report has been split into two separate documents. A background report provides the regulatory framework and describes the various methods and approaches used in the assessment process; this report is expected to change relatively little year on year. The most recent annual assessment (this report) then provides a relatively short description of developments in the latest year together with updated tables and figures. Both reports are available on line at the same location on the Gov.UK website.

It should be noted that the data for the most recent year are provisional and will be updated and confirmed as complete catch data are obtained and records validated. The final confirmed data for the current year will be included in next year's report. The Environment Agency and Natural Resources Wales also publish separate Salmonid and Freshwater Fisheries Statistics reports. These are also available at Gov.UK: <https://www.gov.uk/government/collections/salmonid-and-freshwater-fisheries-statistics>.

HIGHLIGHTS FOR 2015

- The provisional declared salmon catch by nets and fixed engines in 2015 (17,305 fish; 60.3 t) was 44% higher than that taken in 2014 and close to the average of the previous five years. These figures include a small number of fish (209) that were released alive. Most of the catch (92%) was taken in the north east coast fishery. There has been a marked decline in net catches over the past 15-20 years as a consequence of increased regulatory controls and the phasing out of mixed stock fisheries.
- The provisional estimated rod catch in 2015 (12,561 fish) increased by 22% on the confirmed catch for 2014, but remains among the lowest in the available time series. The catch of 1SW salmon (grilse) improved slightly on 2014, but was still second lowest in the available time series. In contrast, the catch of MSW salmon was close to the recent 5-year mean and among the highest in the time series.
- Flows on many rivers were well below average in September and October. Unfavourable conditions for angling at this time are likely to have contributed to the poor rod catches of grilse which return later in the season.
- Since 1993, rod catches include an increasing proportion of fish that have been caught and released. In 2015, it is provisionally estimated that 9,925 salmon (79% of the catch) were released. This is the highest percentage ever recorded. It is estimated that released fish contributed an additional 20 million eggs to the breeding population.
- Since the introduction of the national measures to protect spring salmon in 1999, anglers have been releasing a greater proportion of all fish caught, and of large salmon in particular.
- Returning stock estimates and counts from 9 rivers (Table 23) showed a highly variable picture and suggest north-south differences in salmon returns in 2015. For example, 5 out of 6 rivers in the south reported returns above the recent 5-year average and, for two rivers, these were the highest recorded for over 25 years. In contrast, 2 out of 3 counted rivers in the north had returns that were at or close to the minimum recorded in the respective 24 to 27 year time-series.
- Spawning escapement in 2015 was estimated to be above the conservation limit (CL) in 22 of the 64 principal salmon rivers in England and Wales (34%). This is an improvement on 2014 when only 13 rivers were assessed as meeting their CL, the lowest number in the time series. Rivers where spawning escapement was below the CL were widely distributed throughout England and Wales.
- Formal compliance assessment in 2015 indicated that 9 rivers (14%) were classified within the top two categories – i.e. had a greater than 50% probability of achieving the management objective (MO) of exceeding the CL in 4 years out of 5, on average. No rivers were classified as ‘not at risk’ ($\geq 95\%$ probability of meeting the MO) and 23 rivers (36%) were classified as ‘at risk’ – having a low probability ($p \leq 5\%$) of achieving the MO).
- Salmon with swollen and/or bleeding vents (Red Vent Syndrome) continued to be observed in 2015. Affected fish show a degree of recovery in freshwater and appear to be able to spawn successfully. Fish with fungal infections were also reported from some rivers.

REPORT ON SALMON FISHERIES IN 2015

1. DESCRIPTION OF STOCKS AND FISHERIES

There are 49 rivers in England and 31 rivers in Wales that regularly support salmon (Figure 1), although some of the stocks are very small and support minimal catches; of these, 64 rivers have been designated 'principal salmon rivers'. Conservation limits (CLs) and Management Targets (MTs) have been set for the 42 principal salmon rivers in England and 22 in Wales and are used to give annual advice on stock status and to assess the need for management and conservation measures.

Rod fishing for salmon is permitted on all rivers supporting salmon stocks, and net or fixed engine fisheries operate on a proportion of these, usually in the river estuaries. Descriptions of the different salmon fishing methods employed in England and Wales can be found in the background report.

Many of the tables and figures presented in this report summarise statistics for England and Wales at a regional level. Following a reorganisation in 2014, the Environment Agency ceased to operate on a regional basis. However, in the interests of maintaining existing time series, data are still aggregated and reported on a regional basis in this report. The full statistics, reported on a river by river basis, are provided in the catch statistics reports which are published annually by the Environment Agency and Natural Resources Wales. A list of the individual rivers falling within each region is provided in Table 1.

Table 1. The main salmon rivers in England and Wales aggregated by their earlier regional jurisdictions. The table also provides details of those rivers with Salmon Action Plans and those designated as Special Areas of Conservation (SAC) for which salmon are a qualifying species.

Note: Those rivers designated as SACs have salmon identified as a qualifying species in all or part of the catchment. This confers additional protection measures specifically for salmon in these rivers and any associated on-line lakes. In some of these rivers, salmon are a primary reason for SAC designation.

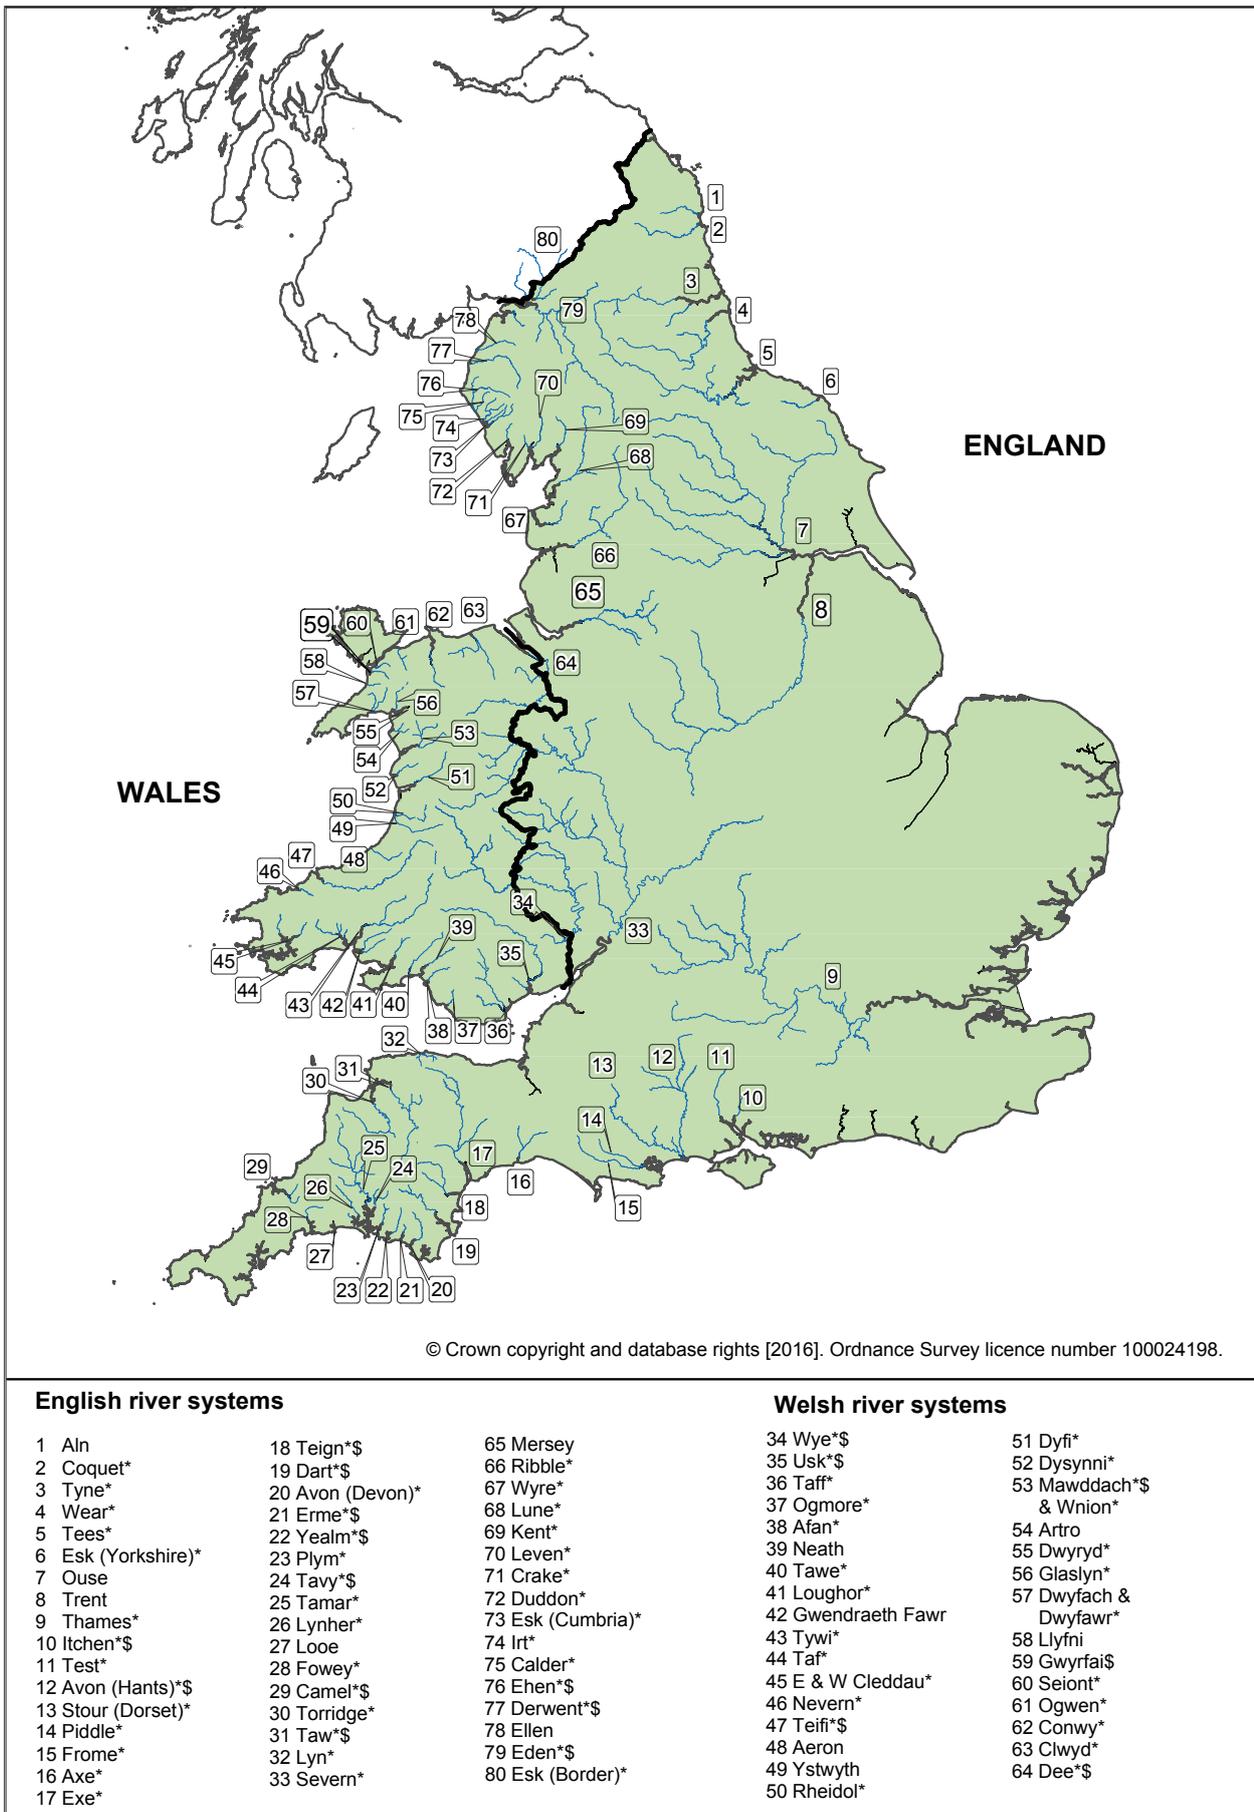

Figure 1. Map of England and Wales showing the main salmon rivers and denoting those with Salmon Action Plans (*) and those designated as Special Areas of Conservation (\$) in which salmon must be maintained or restored to favourable conservation status.

2. FISHERY REGULATION MEASURES

Salmon fisheries in England and Wales are primarily regulated by effort controls, which specify the nature of the gear that may be operated, along with where, when and how it may be used. A full description of these controls is provided in the background report; summary details of the current Net Limitation Orders (NLOs) and byelaws related to rod fisheries are provided in Annex 2 and Annex 3, respectively. The following tables summarise some of the other current controls:

- Table 2 provides details of the rod bag limits and catch limits on net and fixed engine fisheries that are currently in force.
- Table 3 summarises the progress in phasing out those net fisheries that exploit predominantly mixed-stocks where our capacity to manage individual stocks is compromised. A policy to phase out such fisheries has been in place since 1996.
- Table 4 provides details of other arrangements to reduce netting effort operating in 2015, principally by agreement to release fish alive or by compensating netsmen not to fish for the periods shown.
- Table 5 provides a summary of the effort restrictions recorded in Table 4 over the available time series, 1993 – present.

In response to the widespread decline in stocks of early-running multi-sea-winter (MSW) salmon, national measures were introduced in 1999 to reduce the levels of exploitation of this stock component. Most netsmen were banned from fishing for salmon before 1 June, with a small number allowed to continue where netting is predominantly for sea trout, on the basis that any salmon caught are returned alive. The national measures also introduced mandatory catch-and-release of salmon by anglers prior to 16 June and imposed other method restrictions. Following review and consultation, the total package of national spring salmon measures was renewed for a further 10 years in December 2008. A brief evaluation of the effect of these measures is included in Section 4.

Table 2. Statutory rod bag limits and catch limits on net and fixed engine fisheries in force for salmon in 2015.

EA Region / NRW	Rod fishery bag limits				Net/FE catch limits

Note: Bold text denotes target reached.

Key: * Phase out accelerated by full or partial buy-off.

Denotes fishery closed by byelaw.

^(a) Fisheries have not operated for a number of years, now formally closed through byelaw.

^(b) Licences issued but fishermen compensated not to fish in these years.

^(c) Phase out replaced by new NLO in 2012 permitting the use of 1 net.

^(d) Phase out replaced by new NLO in 2013 permitting the use of 2 nets.

^(e) Phase out remains in place, but under new NLO existing licensees able to resume fishing following 10-year buy-off, subject to catch limits.

Table 4. Buy off arrangements operating on net fisheries in 2015

River/ Fishery	Method	Period without netting (full season in parentheses)	Brokers/ Funding agency
Fowey	seine nets (all)	complete season (2007 to present) (2 March–31 August)	Brokered by: Environment Agency / South West Water plc
Piddle and Frome (Poole Harbour)	seine net (all)	All salmon & sea trout caught to be released (2008 to present) (1 June–31 July)	Brokered by: Environment Agency and funded by the Frome and Piddle Association ^{1a)}

Notes: Fowey buy-off - fishing from 2 March to 31 May applies to sea trout only.

^{1a)} Local arrangements apply in respect of provision of compensation.

Table 5. Summary of buy off arrangements and local agreements operating on net fisheries, 1993-2015. (X denotes compensation measure applied; O denotes fishery closed or no licences issued/available)

\$ Agreement for all salmon caught to be released alive.

3. FISHING EFFORT

The regulatory measures outlined above provide overall limits on the 'allowable' fishing effort in England and Wales; this has fallen in recent years as measures have been introduced to regulate exploitation. The amount that both netsmen and anglers actually fish (the 'utilised' effort) also varies due to weather conditions, perceptions about the numbers of fish returning, and other factors. The following tables and figures summarise changes in allowable and utilised effort:

Net fisheries – Table 6 and Figure 2 illustrate the long-term decline in the numbers of licences issued for all types of nets and traps over the period since 1971. The rate of decline in the number of fishing days available, covering a more recent, shorter time period, has been greater over this time as a result of additional effort restrictions on remaining licensees (Figure 3). Table 7 provides details of the allowable and utilised effort in salmon net fisheries for the latest season. The percentage of available days that are utilised varies markedly. Figure 3 also illustrates the overall changes in allowable and utilised effort, and the percentage of available days utilised by netsmen, over the available time series.

Rod fisheries – Numbers of rod licences (annual and short-term) from 1994 are shown in Table 6 and Figure 4. No comparable data are available for earlier years because of changes in licensing arrangements. Regional summaries of the total rod days fished, over available time series, are provided in Table 8 and Figure 5. It should be noted that effort data (days fished) submitted via rod licence returns do not distinguish between times spent fishing separately for salmon and sea trout.

Overview of fishing effort in 2015

There has been a progressive decline in the number of net and fixed engine licences issued, and hence in fishing effort, over the time series. There was a small decrease in the number of licences issued in 2015 compared with 2014 (9 fewer licences issued), with total licence numbers in 2015 the lowest in the time series. For many regions, the percentage of the available days utilised by netsmen in 2015 (regional averages ranging from 24% to 42%) was broadly similar to previous years. Utilised effort increased in the North East, but fell slightly in most other regions. However, there was a particularly marked reduction in the Midlands Region (River Severn) where only 8% of days were used compared with 26% in 2014. This is thought to be related to the introduction of new catch limits for the Severn net and fixed engine fishery. As in previous years, there was marked variation between the levels of utilised effort in individual fisheries, ranging from 91% (Yorkshire coast drift net) to zero, where licences were available but no fishing for salmon took place. The overall percentage of available days utilised by netsmen declined steadily between 2000 and 2009, from a little over 34% to about 20% (Figure 3). However, percentage utilisation increased again after this date and has been around 25-30% since 2010, with some of the higher values associated with relatively good catches. This suggests that the take-up of available fishing opportunities is strongly influenced by catch rates.

The numbers of salmon rod licences issued over the shorter available time series (1994 on) show variable patterns. The number of short term (one-day and eight-day) rod licences issued has shown a modest decline over the period, from a 5-year mean of about 11,000 licences at the start of the period to a 5-year mean of approximately 8,600 recently. There has been greater variation in the number of annual licences issued; these account for the majority of the salmon caught by anglers. Annual licence numbers decreased sharply from over 26,000 in 1994 to about 15,000 in 2001. This was thought to reflect the decline in salmon stocks and the introduction

of restrictions on angling, especially those to protect early-run MSW fish, although licence sales were particularly low in 2001 due to the restrictions on access to many rivers as a result of an outbreak of the 'foot and mouth' livestock disease. Sales of annual licences increased again after this date, reflecting Environment Agency efforts to promote angling and to reduce levels of licence evasion through targeted enforcement efforts. Licence sales in the period 2009 to 2012 were in excess of 26,000, similar to levels at the start of the time period. Since this time, numbers have fallen again slightly. In 2015, about 22,800 annual licences were issued; these data are provisional.

The number of days fished by anglers closely followed the reduction in rod licence numbers over the period 1994 to 2001. However, while annual licence sales then recovered to the levels at the start of the time series, the number of days fished by anglers has not. The number of days has fished fluctuated somewhat from year to year since this time, but without any obvious trend. Provisionally, the overall number of days fished by anglers in 2015 (has been estimated at about 173,000), this is close to the average of the previous five years. There is some variation in the pattern of fishing effort between regions (Figure 5). For Wales and a number of regions in England (North West, South West and Midlands), the number of days fished has fallen by about a half between the start and end of the time series. In contrast, fishing effort in the North East and Southern Regions has remained relatively consistent.

Table 6. Numbers of rod licences (1994-2015) and net & fixed engine licences (1971-2015) in England and Wales.

Year	Rod licences		Gear Type				Total net licences	
	Short-term	Annual	Gill	Sweep	Hand-held	FE		Combined drift/T net #

Notes: Rod short-term licences are for 1 or 8 days; annual licences are valid from the date of issue to 31 March following.

Gill nets include: drift, trammel, sling and coracle nets.

Sweep nets include: seine (draft and draw) and wade nets.

Hand-held nets include: haaf/heave and lave/dip nets.

Fixed engines include: T-nets, J-nets, stop (compass) nets, putcher ranks, traps, weirs and cribs (coops).

East Anglian coastal nets & Southern seine net are not included, as they are targeted primarily at sea trout and catch few salmon.

Table only includes data for gear licences that are fished (i.e. excluding licences that remain available, but which cannot be fished due to compensation arrangements or other similar provisions).

Data for 2015 are provisional.

Key: # Combined drift/T net licences (issued in Northumbria (Northern area)) have been included in the gill net totals.

Key: ^[a] National spring salmon byelaws apply – all net fisheries closed until June 1.

^[b] Sea trout fisheries – exempted from national spring salmon byelaws (all salmon caught before 1 June to be released).

^[c] NLO refers to number of nets allowed under the terms of the net limitation order for that fishery. Where number of licences exceeds NLO, numbers are being reduced as licensees leave the fishery. For coastal mixed stock fisheries a zero NLO means the fishery is being phased out permanently, but for other fisheries the zero limit may only apply for the duration of the NLO.

^[d] Denotes fishery operates under an historical certificate of privilege.

^[e] No NLO, but number of licences capped.

^[f] In calculating the days available, any day, or part day, on which fishing has been allowed is included. Days available have been adjusted to take account of partial buy-off arrangements and the national measures.

^[g] Buy-off applies for all or part season (see Table 4 for details).

^[h] Allowable effort is calculated by multiplying the days available by the number of nets permitted under the NLO, except where the number of licences exceeds the NLO, in which case the higher figure is used.

^[i] Fisheries subject to phase out, but this subject to review in 2017 to see if some level of sustainable fishing by these nets might be retained.

^[k] Fishery subject to seasonal catch limit.

Table 8. Total number of rod days fished, as reported in catch returns, 1994–2015.

Notes: Includes effort targeted at both salmon and sea trout.

Table does not include rod days fished in the Anglian Region, where there are not thought to be any directed rod fisheries.

Rod catch and effort data for 2015 were, in part, derived from a new on-line catch reporting system.

Some concerns have been raised about the completeness of the resulting data, and a correction factor has therefore been derived and applied to such data in all Regions.

Data for 2015 are provisional.

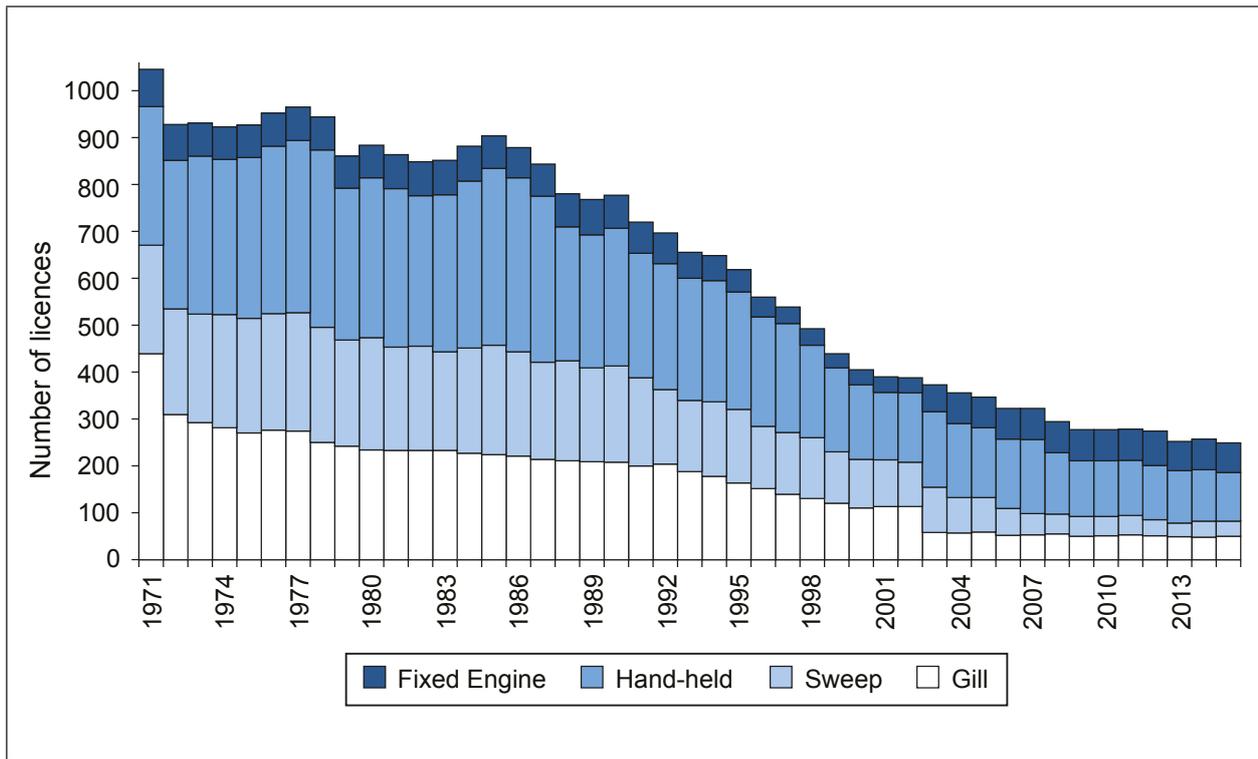

Figure 2. Numbers of salmon net & fixed engine licences issued in England and Wales, 1971–2015.

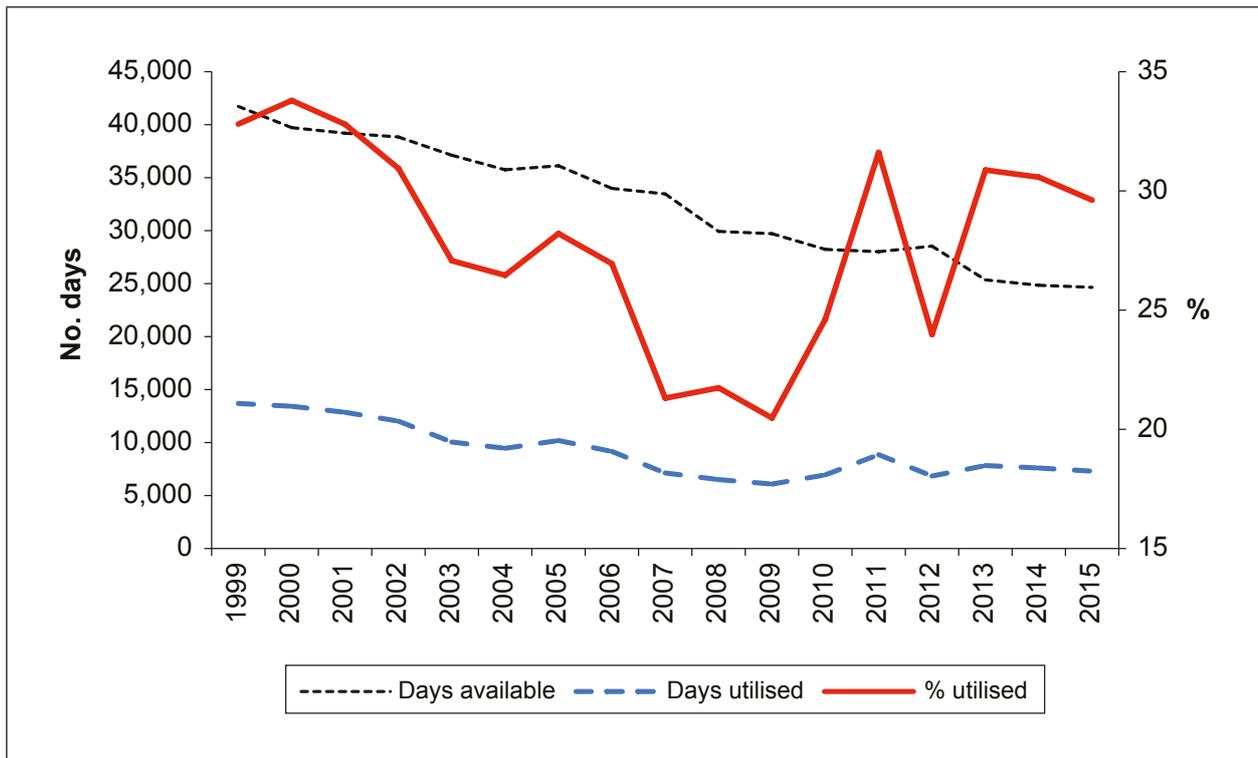

Figure 3. Numbers of fishing days available to net and fixed engine fisheries in England and Wales, and number and percentage of available days utilised, 1999–2015.

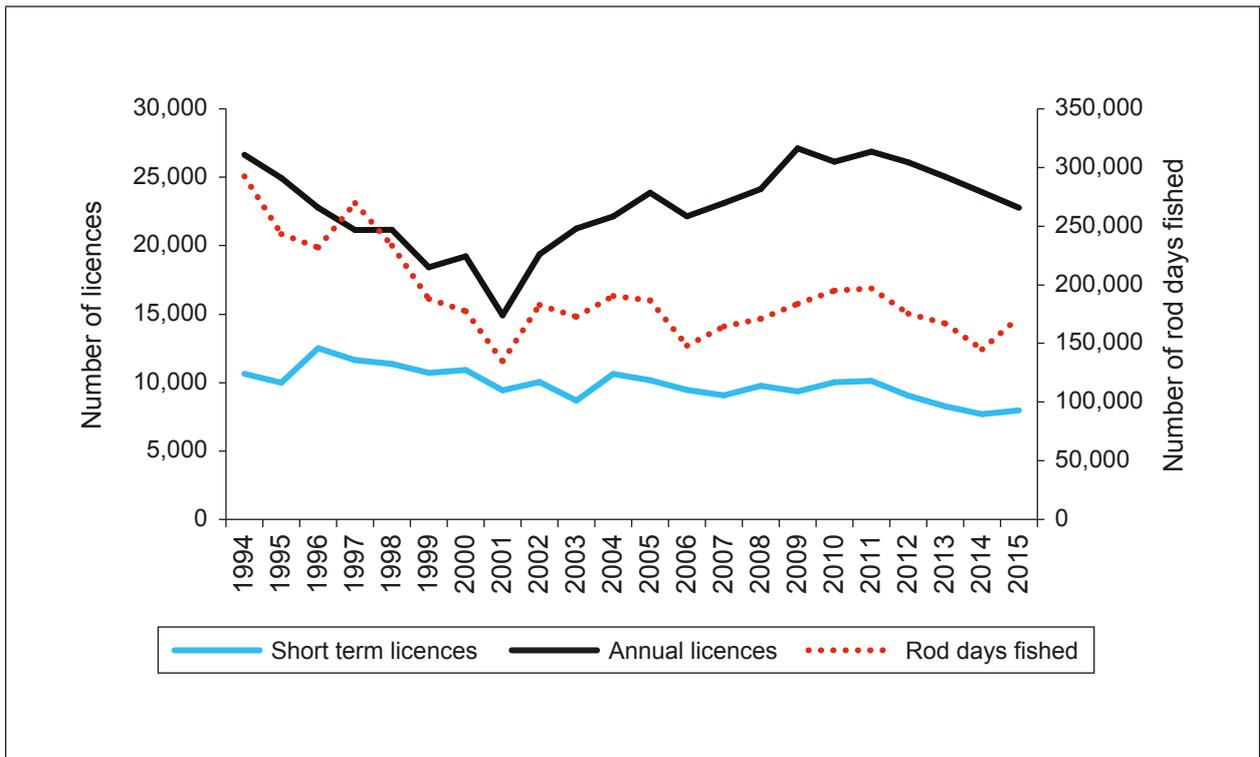

Figure 4. Numbers of annual and short-term rod licences issued, and the number of rod days fished in England and Wales, 1994–2015.

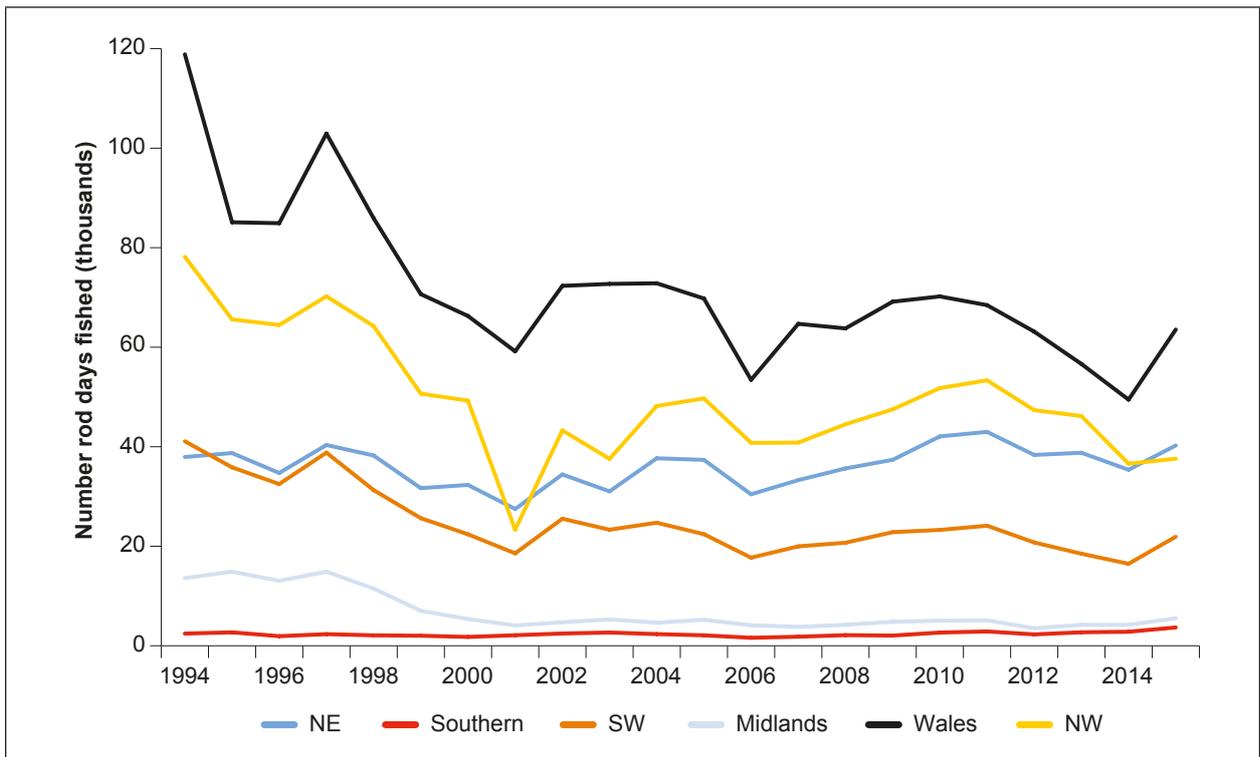

Figure 5. Numbers of rod days fished (as reported in catch returns), 1994–2015.

4. DECLARED CATCHES

The chief indicators of the state of salmon stocks are the catches taken by rod and net fisheries. It should be remembered that the data presented here for 2015 are provisional. Final confirmed data for 2015 will be reported in the Environment Agency and Natural Resources Wales annual compilation of catch statistics, which will be available later in the year (see, for example, Environment Agency, 2015).

Assessment of rod catch data for 2015 identified some potential data accuracy issues which may be associated with changes to the rod catch reporting system. To account for this apparent discrepancy, an additional correction factor (1.24) was derived and applied to the provisional declared rod catches for 2015 in all regions. A more detailed description of the methodology used in this adjustment process, as well as of the catch reporting procedures for both net and rod fisheries, is provided in the background report.

Net and rod fisheries – The following tables and figures provide estimates for 2015 together with confirmed catches for earlier years:

- Table 9 provides the total declared number and weight of salmon caught by nets & fixed engines and by rods in England and Wales since 1988, and provides overall catch totals for England and Wales for both total catch and retained catch (excluding fish that have been caught and released).
- Table 10 gives a regional breakdown of the provisional 2015 rod and net catches (based on the former Environment Agency regions). These data are total catches only and include fish that have been caught and released by both nets and rods.
- Table 11 and Figure 6 provide time series of regional net and fixed engine catches (retained fish only) from 1971 on.
- Table 12 and Figure 7 provide time series of regional rod catches from 1993 on, distinguishing fish caught and released from those caught and retained (data on catch-and-release were not recorded prior to 1993).

Catches in coastal, estuary and river fisheries – ICES requests that catch data (fish caught and retained only) are grouped by coastal, estuary and river fisheries. Data for the available time series, since 1988, are presented in Table 13 and Figure 8. Details of the fisheries included in the various categories are provided in the footnotes to the table. The catch for the coastal zone mainly reflects the catch in the north east drift and fixed net fishery. Only two coastal fisheries remained in operation in 2015 and one of these, Anglian, takes very few salmon (Table 11). The catches in each of the categories have been subjected to downward pressures over recent years, in the case of the coastal and estuarine categories due to the substantial reductions in fishing effort, and, in the case of rod fisheries, due to the increasing use of catch and release.

Catch and release (C&R) – C&R data were first collected in England and Wales in 1993, and the practice has been used increasingly by salmon anglers in recent years. This is largely a result of voluntary measures, but also reflects the national measures to protect spring salmon and the introduction of mandatory C&R on some rivers (details available in Annex 3). Regional C&R rates are provided in Table 12 and Figure 7 and a summary for England and Wales as a whole is given in Table 14 and Figure 9. C&R rates for each major salmon river in England and Wales are published in the annual catch statistics.

Long-term catch trends – The annual declared net and fixed engine catch for England and Wales since 1956 is shown in Figure 10; this distinguishes the catch taken in the north east coast fishery from net catches elsewhere. Figure 11 presents the declared rod catch of salmon from 1956, including (since 1993) fish that have been caught and released. It is unclear to what extent fish may be caught and recorded more than once as a result of C&R.

Undeclared and illegal catches – The non-reported and illegal catch for England and Wales in 2015 is estimated at about 13 tonnes, which represents approximately 16% of the total weight (including the unreported and illegal catch) of salmon caught and killed. Of the total unreported and illegal catch in 2015 (approximately 3,400 salmon), 53% by number is estimated to have derived from illegal catches, 37% from under-reporting in rod fisheries and 10% from under-reporting in net fisheries. The methodology used to derive these crude estimates is provided in the background report. No other substantial sources of non-catch fishing mortality, such as reports of significant mortalities of fish in rivers / estuaries due to elevated temperatures or water quality issues, were noted in 2015. There were, however, reports of fish with fungal infections in some rivers (Section 10).

Effect of the national spring salmon measures – The restrictions imposed as a result of the national measures, since 1999, have affected both net and rod fisheries. Table 15 and Figures 12a (nets) and 12b (rods) show the reduction in the number of fish caught before June. Table 16 and Figure 13 show the numbers of salmon released by weight category (<3.6 kg (8 lbs), 3.6–6.4 kg, and >6.4 kg (14 lbs)) and season, since 1998. This illustrates that anglers have been voluntarily releasing an increased proportion of all fish caught after June, and large salmon in particular.

Age composition of catches – The annual salmon stock assessments carried out by ICES are conducted on two separate stock components: those fish that mature after one winter at sea (i.e. one-sea-winter fish / 1SW or grilse) and those that mature after two or more years at sea (i.e. multi-sea-winter / MSW fish). The relative proportions of the different sea-age groups have shown marked variability over time (Figure 14), and the different sea-age classes tend to have different patterns of run-timing. It is therefore necessary to be able to estimate the relative proportions of 1SW and MSW fish in catches; details of the approaches used are provided in the background report.

- **Nets** – The relative proportions of 1SW and MSW fish in regional net catches in 2015 are provided in Table 17 and available time series are presented in Figures 15 and 16. The longer time series for the North East Region reflects the consistent reporting arrangements that have applied in this fishery since the mid-1960s.
- **Rods** – The estimated age composition of catches for many of the principal salmon rivers in 2015 is provided in Table 18. Of these, 13 rivers (32%) were estimated to contain 50% or more MSW salmon (including fish subsequently released), 23 rivers (56%) had between 25% and 50% MSW salmon and 5 rivers (12%) less than 25% MSW salmon in the rod catch. Changes in the relative proportions of fish in these different categories (for the same rivers) are presented in Figure 17.

The estimated numbers of 1SW and MSW salmon (including fish released), and the percentage of MSW fish, in regional rod catches over the period since 1992 are provided in Table 19; these data have been corrected for under-reporting – a scaling factor of 1.1 is typically applied (see background report for details). The number and percentage of MSW salmon in regional rod catches are illustrated in Figure 18. A summary of the estimated rod catch of 1SW and MSW salmon for England and Wales as a whole, for the same period, is provided at Figure 19.

Overview of catches in 2015

The total salmon catch for 2015 (including those fish released alive by netmen and anglers) is provisionally estimated at 112.4 t, representing 29,866 fish, and comprising 60.3 t (17,305 fish) by nets and fixed engines and 52.1 t (12,561 fish) by rods. A total of 209 fish (0.8 t) were released from nets and fixed engines. Of the rod caught fish, 9,925 were released (42.2 t), representing 79% of the catch by number. Thus, 17,096 fish (59.5 t) were retained by netmen and 2,636 fish (9.8 t) were retained by anglers. These figures do not take account of catches of salmon which go unreported (including those taken illegally), and it is estimated that there may have been a total of 13 t of additional fish caught in 2015.

The total declared catch by nets and fixed engines in 2015 increased by 44% on the catch recorded in 2014, and was very close to the average of the previous five years. There has been a marked decline in net catches over the past 15-20 years as a consequence of increased regulatory controls and the phasing out of some fisheries.

The policy to phase out salmon fisheries predominantly exploiting mixed stocks, where the capacity to manage individual river stocks is compromised, has had a major effect on catches. The largest phase out has occurred in the north east coast fishery. This was enhanced by a partial buy out in 2003, which reduced the number of drift net licences from 69 in 2002 to 16 (an immediate reduction of 77%). The ongoing phase out has resulted in the number of drift net licences continuing to fall; this currently stands at 12. The T/J nets have also been subject to a reducing NLO since 2012 with licence numbers falling from 63 in 2012 to 49 currently. Despite this, the north east coast fishery still accounts for the majority of the England and Wales net catch. In the past five years, the fishery has accounted for between 86% and 93% of the total net catch (92% in 2015).

The provisional estimated rod catch in 2015 (including released fish) increased by 22% on 2014, but remained over 30% below the average of the previous 5 years. Long-term trends in rod catch (Figure 11) indicate a progressive decline from the peak in the mid-1960's to the early 2000's. This was followed by a general improvement in the rod catch between 2004 and 2011, suggesting some degree of reversal in the declining trend, when catches, including fish caught and released, were typically above the long-term average. However, there has been a decline in catches since 2012 and the provisional rod catch for 2015 remains among the lowest in the entire time series. Low flows and poor conditions for angling likely contributed to this low catch (Section 9.2). It should also be noted that rod catch trends on individual rivers have varied from much more severe declines to substantial recoveries. The percentage of rod caught fish released by anglers has increased progressively since such data were first recorded in 1993; it is provisionally estimated that 79% of rod caught fish were released in 2015.

Rod catches of 1SW salmon show substantially greater year to year variability than those of MSW fish in numerical terms (Figure 19). Since the early 1990s, catches of 1SW salmon have ranged from a high of over 24,200 to just 5,600. Catches in the period 2004 to 2011 were generally higher than those in the early part of the time series. However, there has been a sharp downturn in the 1SW rod catch in the last four years, with the provisional declared catch in 2015 being the second lowest in the time series, the lowest being in 2014. In contrast, rod catches of MSW salmon have demonstrated comparatively small numerical changes (range 3,100 to 10,900), and have been trending positively over the period as a whole. Catches of MSW salmon

in 2015 were among the highest in the time series, and MSW salmon have comprised 46% of the total rod catch, on average, in the last five years, compared with an average of 25% in the preceding period back to 1992.

Assessment of national catch trend

The annual assessment of the status of salmon stocks in the northeast Atlantic carried out by the ICES North Atlantic Salmon Working Group, requires the best available time series of nominal catch data (i.e. fish retained) for each country. Figure 20 provides the current best estimate of the total catches of 1SW and MSW salmon in England and Wales, for the period since 1971. These data have been adjusted to take account of non-reported and illegal catches, and exclude Scottish origin fish taken in the north east coast fishery. Further details on the procedures used in deriving these estimates are provided in the background report.

The data indicate that catches of salmon in England and Wales (fish caught and killed only) have declined by over 85% from the early 1970s to the present time. There was a particularly marked decline in catch around 1990, which is consistent with the general perception of a decrease in the marine survival for many stocks around the North Atlantic, and consequently in the abundance of returning fish, at about this time. For much of the period, the decline has been greater in the non-maturing (i.e. potential MSW) fish than for the maturing (i.e. potential 1SW) component. However, there has been a marked increase in the proportion of MSW salmon in the catch in the last five years (Figure 20) and the overall reduction in catches between the start and end of the time series is now very similar (~85%) for both age groups of fish.

Table 9. Declared number and weight of salmon caught by nets & fixed engines and by rods in England & Wales, 1998–2015.

Mean (2010–14)	57.0	65	5.9	7	25.2	29	88.2

Notes: Coastal catches in 2015 from North East coast nets and Anglian coastal nets, but previously included River Parrett putcher rank (last fished 1999), River Usk drift nets (1997) & putcher rank (1999), SW Wales coastal wade (1995) & seine nets (1997), River Ogwen seine nets (2000), River Seiont/Gwyrfaï seine nets (1997), River Dwyfawr seine nets (1999), N. Caernarvonshire seine nets (1996), River Clwyd sling (drift) nets (1997) and the SW Cumbria drift nets (2003). Riverine catches in 2015 from rod catches and River Eden coops; River Conwy basket trap (also operated in freshwater) was last fished in 2002. Estuarine fisheries include all other nets and fixed engines not mentioned above. Data for 2015 are provisional.

Table 14. Declared number, weight and percentage of salmon released by rods, and declared number and weight of salmon released by nets, 1993-2015.

Year	Salmon released by rods			Salmon released by nets	
	Number released	Weight (t)	% of declared catch	Number	Weight (t)

2012	11,952	53.89	65	56	0.2
2013	10,458	45.26	70	30	0.1
2014	7,992	34.19	78	73	0.2
2015	9,925	42.22	79	209	0.8

Notes: A proportion of the salmon released by nets are fish caught pre June, which, since 1999, are required to be released. Catch limits now apply on a number of net and fixed engine fisheries necessitating salmon to be released once limits are reached.

A small proportion of the salmon released by nets have previously resulted from an agreement between the Environment Agency and netmen fishing the estuary of the River Avon (Hants); this fishery ceased to operate in 2012.

There was no requirement for net caught salmon to be released prior to 1999.

Data for 2015 are provisional.

Table 15. Declared number and percentage of salmon caught by nets and rods taken before (<) and from (≥) 1 June, 1989–2015.

Year	Net catch (including released fish)				Rod catch (including released fish)			
	Number			%	Number #			%

Notes: National measures to protect 'spring' salmon introduced on April 15 1999 – required compulsory catch and release of all rod caught salmon prior to June 16, and closed most net fisheries prior to June 1. Those net fisheries still allowed to operate before June (mainly targeted at sea trout) are required to release all salmon alive.

Rod catch data for 2015 were, in part, derived from a new on-line catch reporting system. Some concerns have been raised about the completeness of the resulting data, and a correction factor has therefore been derived and applied to rod catches in all Regions.

Data for 2015 are provisional.

Key: # Excludes fish for which no capture date recorded.

^[a] No requirement to record net-released fish on new logbooks, so pre-June catch under-estimated.

^[b] The increase in the pre-June catch from 2011 reflects the fact that salmon caught and released by T&J nets operating in the NE Region were not recorded over the period 1999-2010.

Table 16. Declared number of salmon caught by rods, and number and percentage of fish released, by weight category and season, 1998–2015.

Notes: 1998 Pre national byelaw.

1999 National byelaw requiring compulsory catch and release before 16 June introduced on 15 April.

2000 First full year of national catch and release byelaw.

Analysis based on representative sample of catch return data; totals differ from the declared catches (Table 10).

Data for 2015 are provisional.

Table 17. Provisional declared number and percentage of small (<3.6kg) and large (>3.6kg) salmon caught by net fisheries, 2015 (excluding released fish).

EA Region/NRW	Small salmon (1SW)		Large salmon (MSW)		Total
	(<3.6 kg)	%	(>3.6 kg)	%	
North East	5,053	64	2,896	36	7,949
South West	266	68	128	32	394

5. CATCH PER UNIT EFFORT (CPUE)

Since catch levels are influenced strongly by the level of fishing effort, catch per unit effort (CPUE) data are commonly used as well as the declared catch in order to help evaluate the status of stocks. However, the relationship between CPUE and abundance can be influenced by confounding factors in both rod and net fisheries. It should also be remembered that net and rod fisheries operate sequentially (the net fisheries exploit the returning fish first), and over different time periods (fishing seasons). Rod fisheries are active over a longer period and typically extend into the early autumn after net fisheries have ceased to fish. Thus, changes in patterns of run-timing may also impact on CPUE values in the different fisheries.

- **Nets** – Regional CPUE data for net fisheries for the period since 1997 are presented in Table 20. These data are based on the number of tides fished by netmen, except in the North East Region where the number of days fished is used. In order to provide comparable time series, the data only include fishing gears that have operated in a consistent manner over the full period. Plots of the standardised CPUE Z-scores for the various regions and for net fisheries overall (expressed as a 2-year moving average) are provided in Figure 21.
- **Rods** – Regional CPUE data for rod fisheries for the period since 1997 (expressed as the number of salmon caught per 100 days fished) are presented in Table 21. Plots of the standardised CPUE Z-scores for the various regional rod fisheries and the overall rod CPUE for England and Wales are provided in Figure 22 for the same period. Individual CPUE data for all the major salmon rivers in England and Wales are reported in the annual catch statistics reports (e.g. Environment Agency, 2015). The trends in rod CPUE for the different regions show a reasonable degree of coherence and available evidence from selected rivers where we have estimates of returning stock size, as well as CPUE, suggests rod CPUE values provide a reasonable indicator of stock abundance (Figure 23).

Overview of CPUE in 2015

The overall catch per unit effort (CPUE) for nets and fixed engines in 2015 increased on 2014, but was slightly lower (down 5%) than the previous 5-year mean (2010-2014). CPUE in 2015 was well below the 5-year average in Wales, but relatively close to the 5-year mean in other regions (Table 20). Normalised CPUE values (Z-scores) for the various former regions and an overall average (Figure 21) indicate that CPUE, and by inference abundance, peaked during the period 2000-02, then declined steadily until 2009 (which had the lowest CPUE of the time series), before increasing again between 2010 and 2011. Since that time overall CPUE has oscillated; in 2015 it was above the long-term average. An earlier analysis of net CPUE and river flow suggests above average flows in July (when a high proportion of the net catch typically occurs) tend to result in reduced CPUE values.

Rod CPUE in 2015 improved on 2014 in most regions, with particularly large increases evident in the Midlands and South West Regions; in these two regions, and also in the Southern Region, rod CPUE was above the 5-year average (Table 21). In contrast, CPUE in the North East Region fell in 2015 and CPUE values here and in the North West Region and Wales were well below the 5-year average. Normalised CPUE values (Z-scores) for rod fisheries (Figure 22) indicate a largely positive trend between 1997 and 2012, and by inference increasing abundance (Figure 23). However, there has been a downturn in overall CPUE in the last three years.

Notes: Fisheries were selected on the basis that they were fished consistently during the period. Data are expressed as catch per licence-tide, except for the North East, for which data are recorded as catch per licence-day. From 2012, the fishery operating in the Severn (Midlands Region) has been limited by a catch limit (cap); the Midlands data have therefore been removed from the combined E&W total for the whole time series. Data for 2015 are provisional.

Notes: Based only on catch returns for which effort data have been reported.
 CPUE is expressed as number of salmon (including released fish) caught per 100 days fished.
 Data for 2015 are provisional.

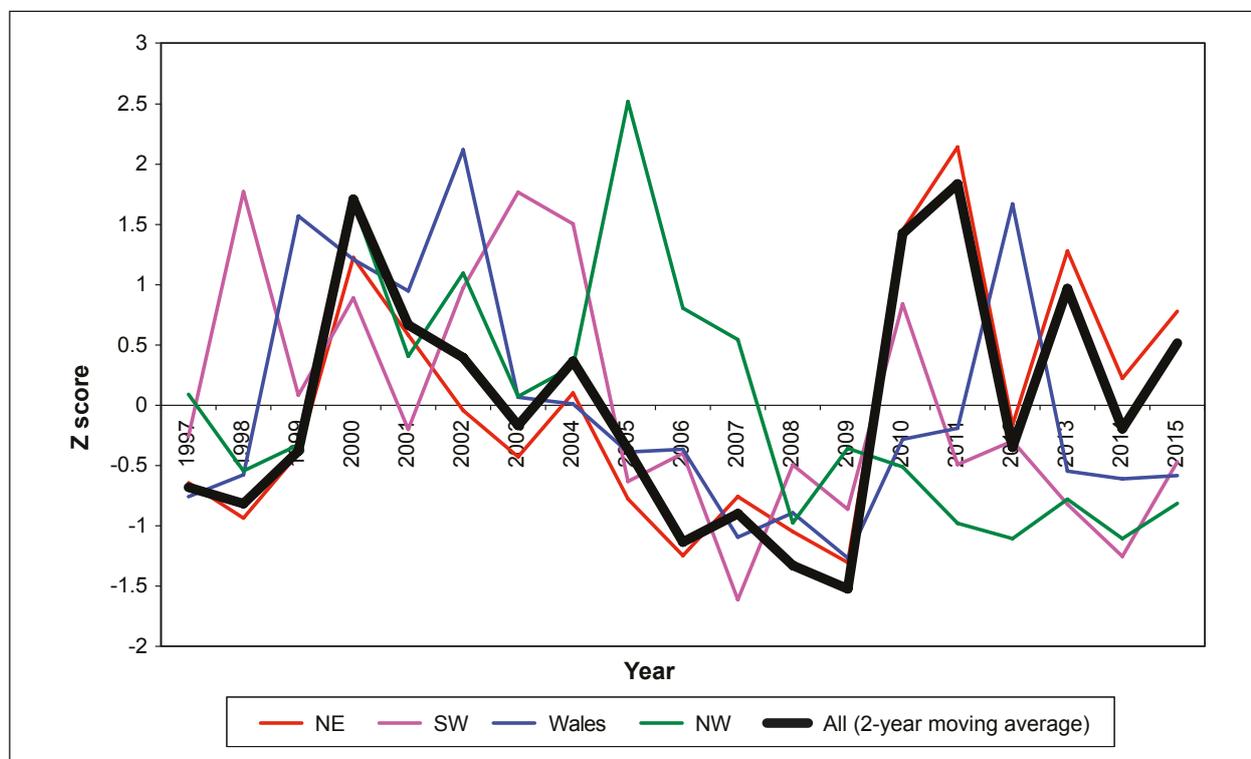

Figure 21. Normalised catch per unit of effort (CPUE) (z-score) for salmon net fisheries, 1997–2015.
 Note: the bold black line for all fisheries has been smoothed using a 2-year moving average.

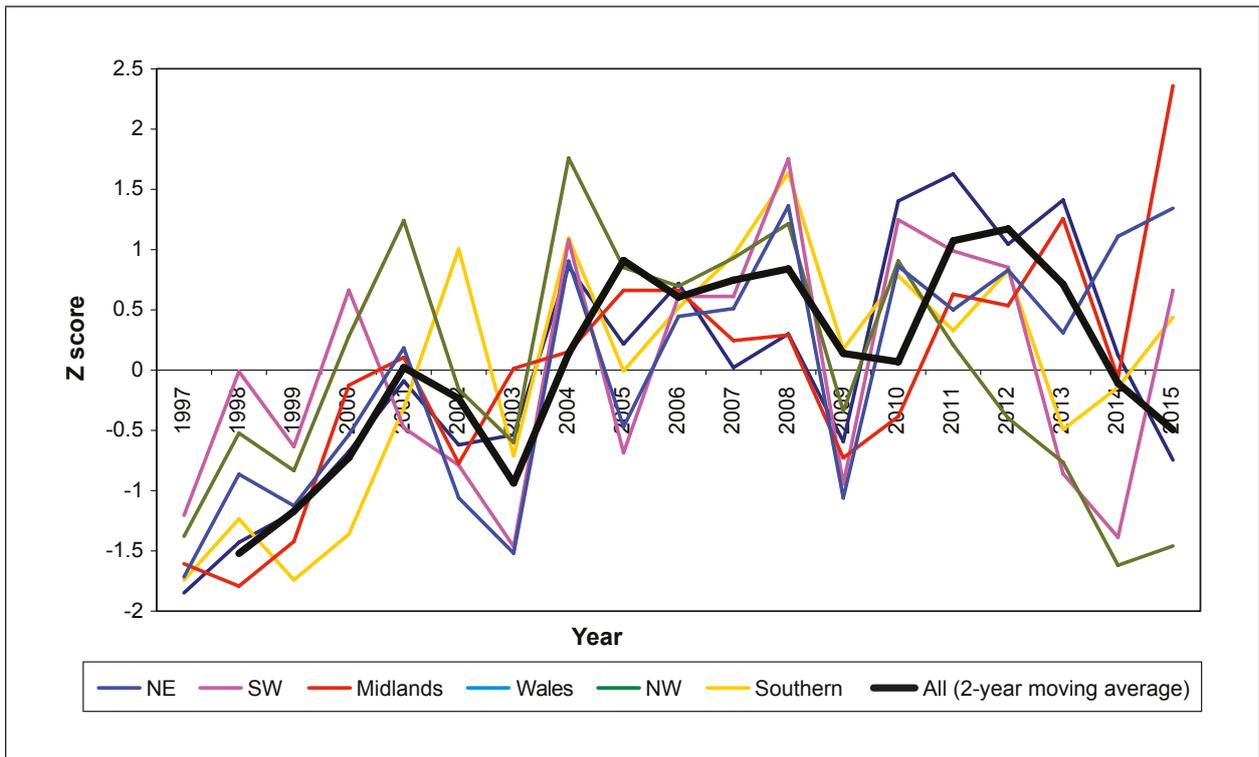

Figure 22. Normalised catch per unit of effort (CPUE) (z-score) for salmon rod fisheries, 1997–2015. Note: the bold black line for all fisheries has been smoothed using a 2-year moving average.

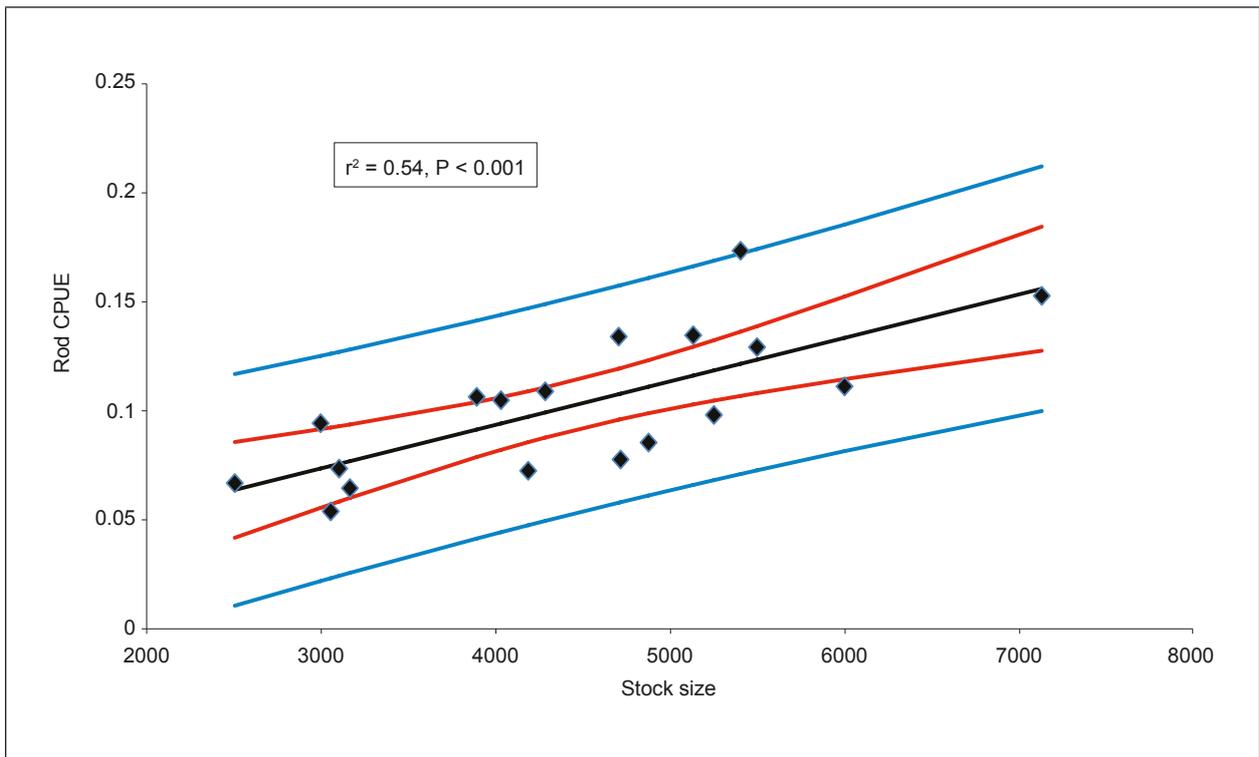

Figure 23. The relationship between mean rod CPUE and mean stock size for the Rivers Fowey, Dee and Lune, 1997–2014. Note: the red lines are 95% confidence intervals and the blue lines 95% prediction intervals.

6. EXPLOITATION RATES

Care is required in trying to draw general conclusions about current stock status from catches alone. The actual relationship between catch and stock abundance depends upon exploitation rates (i.e. the proportion of the salmon population taken in the catch – both retained fish and those released), although it is important to remember that fishing effort and catchability (the proportion of the stock taken per unit of fishing effort) can be influenced by factors such as river flow, angler activity and changes in run timing. Exploitation rates can be estimated where there is a fishery-independent measure of the salmon run, such as that obtained from fish counters and traps (Table 24 and Figure 28), and these data can then be compared against the catch (both total catch and retained fish) to estimate exploitation rates (Table 22 and Figure 24). These show varying trends, but the ‘true’ exploitation rates (i.e. fish retained) show a marked decline in most rivers over the available time series, due largely to the increasing use of catch-and-release.

Overview of exploitation rates in 2015

There was considerable variability in the exploitation rates in rod fisheries in 2015. In most rivers, exploitation rates were higher than those in 2014, with some values also above the average of the previous five years. In other rivers, exploitation rates fell. This pattern is consistent with the variable runs of fish reported for different rivers (Section 7). Low flows and poor conditions for angling in many catchments are also expected to have affected exploitation rates (Section 9.2). While total exploitation rates remain quite high on some rivers, the ‘true’ exploitation rates (i.e. fish retained) show a marked decline over the available time series in almost all rivers. This is largely attributable to catch and release, which has increased from 10% to almost 80% over the past 2 to 3 decades, with mandatory catch and release now applying on some rivers. The exploitation rates for the net fisheries where estimates have been possible have either been reduced to zero or been greatly reduced, largely reflecting a major reduction in effort.

Assessment of national trend in exploitation

Estimates of aggregated national exploitation rates, split by sea-age class, are required for use in the ICES annual assessment of stock status to estimate numbers of returning fish. The procedures used in deriving these estimates are described in the background report. The overall trends in national exploitation rate derived from this process are provided in Figure 25. These indicate that exploitation rates have fallen from about 50% for 1SW fish and 35-40% for MSW fish at the start of the period to 15% and less than 10%, respectively, in recent years due to the measures taken to control both legal and illegal fisheries. The decline in exploitation rates occurred particularly in the 1990s, but has levelled out more recently.

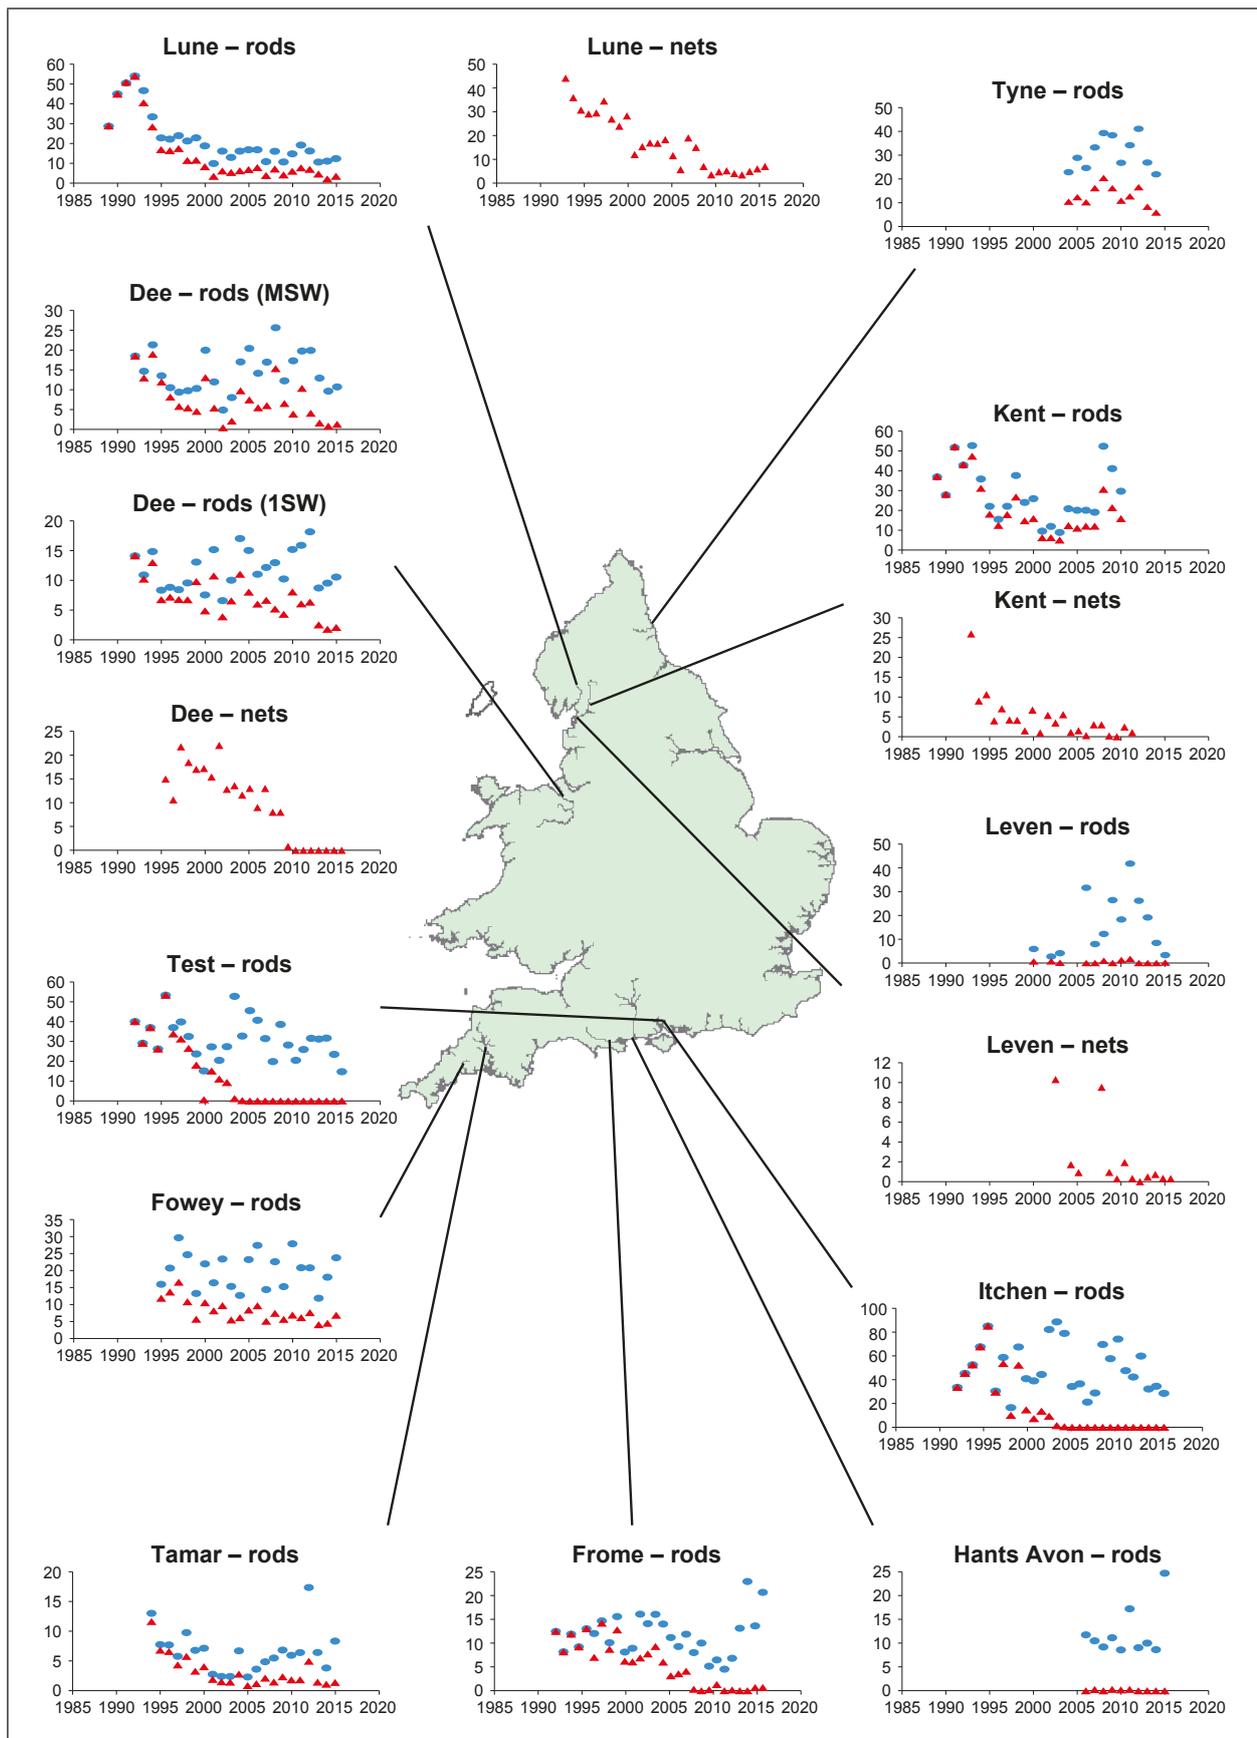

Figure 24. Estimated exploitation rates (%) for selected rod and net fisheries in England & Wales, 1998–2015. For rod fisheries, the figures display exploitation rates for all fish caught – i.e. including fish released (blue dots) and fish killed (red triangles). Note that estimates for the Dee rods have been split by sea-age class (1SW and MSW), all other estimates are combined for all ages. Data for net fisheries are for retained fish only.

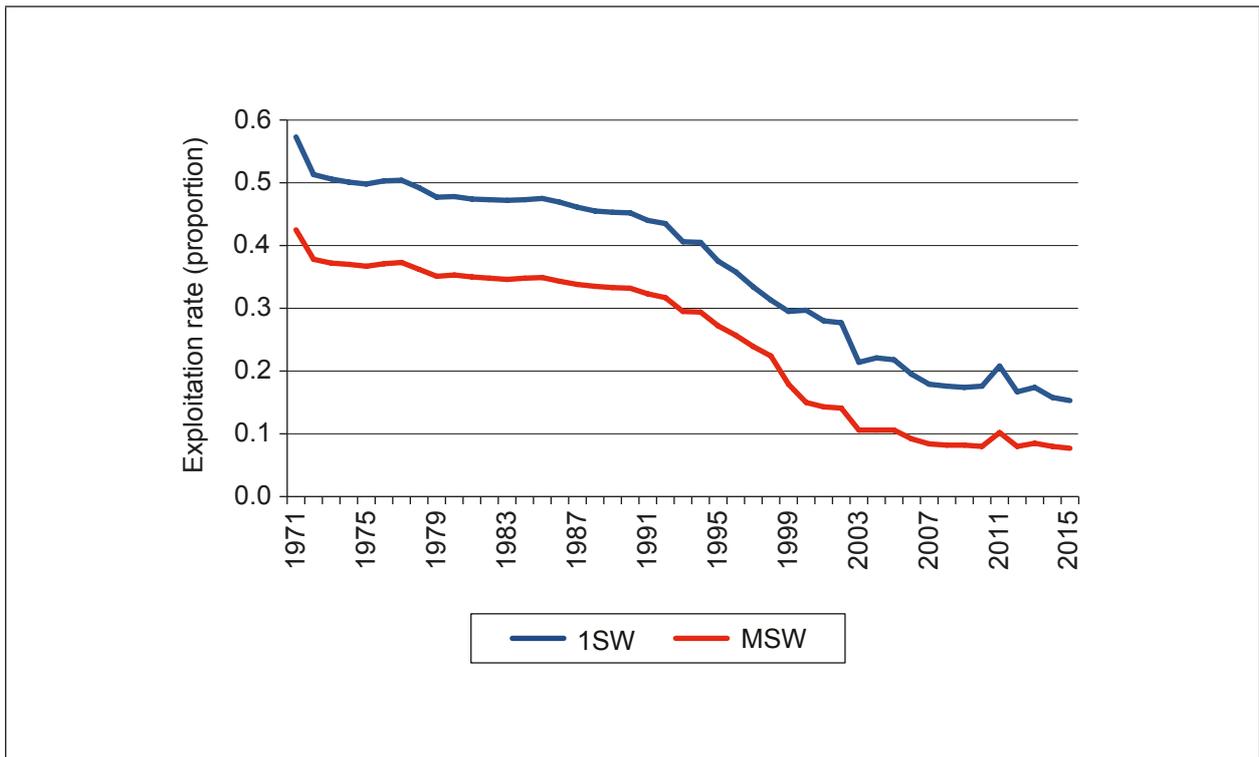

Figure 25. Estimated national exploitation rates for 1SW and MSW salmon caught in England and Wales (fish caught and killed only), including estimated non-reported catch, 1971-2015, as used in the ICES PFA assessment.

REPORT ON STATUS OF STOCKS IN 2015

7. STOCK MONITORING

The Environment Agency and Natural Resources Wales monitor both stocks and fishery performance in most rivers supporting salmon stocks in England and Wales. This includes operating counters, undertaking surveys of juvenile fish and collecting fishery statistics. These data provide the basis for assessing stock status and informing management decisions. In addition to protecting the abundance of stocks, managers need to maintain the diversity of stocks in terms of their biological characteristics. Measures of stock diversity potentially encompass a wide range of biological characteristics, but those of greatest significance for the management of stocks are the population structure within the river, the river-age of the emigrating smolts and the run-timing and sea-age composition of the returning adult stock. Such data tend to be derived from a small number of 'indicator' rivers. Further details on the various monitoring programmes are provided in the background report.

Juvenile surveys (salmon fry and parr)

A programme of juvenile salmonid monitoring is carried out to identify spatial variation in juvenile populations and temporal trends in their abundance. The habitat at all sites is assessed such that the abundance of the juvenile salmon population at any site can be compared with standard reference conditions. A classification scheme is also applied such that the proportion of sites falling into different salmon abundance classes (Classes A to F) provides a measure of the health of the juvenile salmon populations for each river. Figure 26 presents the proportion of sites in each catchment that fall into the top three categories (Classes A to C) over the period 2010 to 2015. Thus, for catchments shaded red, less than 25% of sites fall within this category, while for those shaded green more than 75% of sites are at or above average. Overall, the majority (63%) of sites surveyed over the period were in the lowest two classes (Classes E or F). The proportion of sites surveyed that fell within Classes A to C varied between regions from 7% to 54%. Work is continuing to revise and update the procedures for collecting and interpreting juvenile data.

Figure 27 presents annual estimates of the overall percentage of sites falling within classes A to C viewed over the available time series. There is no clear trend in the data.

Upstream counts of adult salmon

Electronic fish counters or traps are operated on a number of catchments to provide estimates of the upstream run of adult salmon and sea trout. Where it is possible to separate the species, the counts are adjusted to provide estimates of the numbers of returning salmon. For some rivers (e.g. River Tyne) the time-consuming validation procedures mean data may not be available for the latest year. A number of facilities have also ceased to operate in recent years as a result of changes in operating procedures, counter / trap damage or due to budgetary restrictions. Available time series, including those that have been recently discontinued, are presented in Table 23 and Figure 28.

The returning stock estimates and counts showed a highly variable picture and suggest north-south differences in salmon returns in 2015. Five out of the six rivers in the south reported returns above the recent 5-year average and two rivers had a particularly notable upturn (Test and Itchen), recording their best runs for over 25 years. However, the River Dee had the lowest returning stock estimate in the 24-year time series and the River Lune estimate was also among

the lowest in a 27-year time series. There also appear to be marked differences in the trends over time, with some rivers showing an increasing trend (e.g. Test, Itchen and Leven), while others indicate a decline, particularly in more recent years (e.g. Caldey, Lune and Dee).

Tagging investigations

Tagging studies have often been employed to monitor stocks and to evaluate the outcome of different management initiatives, although tagging effort has fallen in recent years. In 2015, around 6,500 wild salmon smolts were microtagged and released in England and Wales to assess levels of marine survival; all these fish were also adipose fin-clipped. A further 23,500 hatchery parr and 9,500 wild parr were marked with adipose fin clips; the wild parr were also fitted with PIT tags. In addition, about 600 adult salmon were tagged for the assessment of returning stocks or in conjunction with the use of radio and acoustic tags in behaviour studies. Details of the tagged and marked salmon released each year around the whole North Atlantic are compiled annually by ICES. Details of the fish tagged in England and Wales in 2015 are provided in Table 24.

Marine survival

Evidence from monitored rivers around the North Atlantic indicates that the survival of salmon during the marine phase of their life-cycle has declined in recent decades. Time series of marine survival estimates, measured as percentage return rates, are shown in Table 25 for the River Corrib (Ireland), River Bush (Northern Ireland) and River North Esk (Scotland) (data from ICES, 2016). Shorter time series for the Rivers Dee (Wales), Tamar and Frome (Table 25 and Figure 29) indicate similar low levels of marine survival in recent years. It was not possible to monitor adult returns on the Tamar in 2014, or to undertake any smolt tagging, so there are therefore gaps in this time series. However, this programme resumed in 2015.

For the River Frome (this was the only 1SW survival estimate available in 2015), the return rate of 1SW fish (from the 2014 smolt cohort) increased slightly on the previous year, but remained among the lowest in the time series. This indicates continued poor survival of 1SW fish and is consistent with the low proportion of 1SW in the 2015 catch. Survival estimates for 2SW salmon in 2015 (from the 2013 smolt cohort) were available for the Dee, Tamar and Frome; with values in each case at the upper end of the ranges of recently observed values. Again, this is consistent with the relatively good returns and catches of MSW salmon.

Analysis of data for the River Dee has previously indicated a clear correlation between survival rates of particular smolt cohorts and the condition of the adult salmon returning to the river derived from these cohorts. This suggests a direct link between the ability of salmon to feed and grow at sea and their subsequent survival.

Counts from electronic counters (C) and monitoring traps (T), and returning stock estimates (RSE) (based on trapping and tagging, or validated counts plus catch below counter) for selected salmon stocks in England and Wales, 1988–2015. Regression lines are indicative only and based on data from 1995 on (red squares); earlier date for some rivers indicated as blue diamonds. Note that y-axes scales differ.

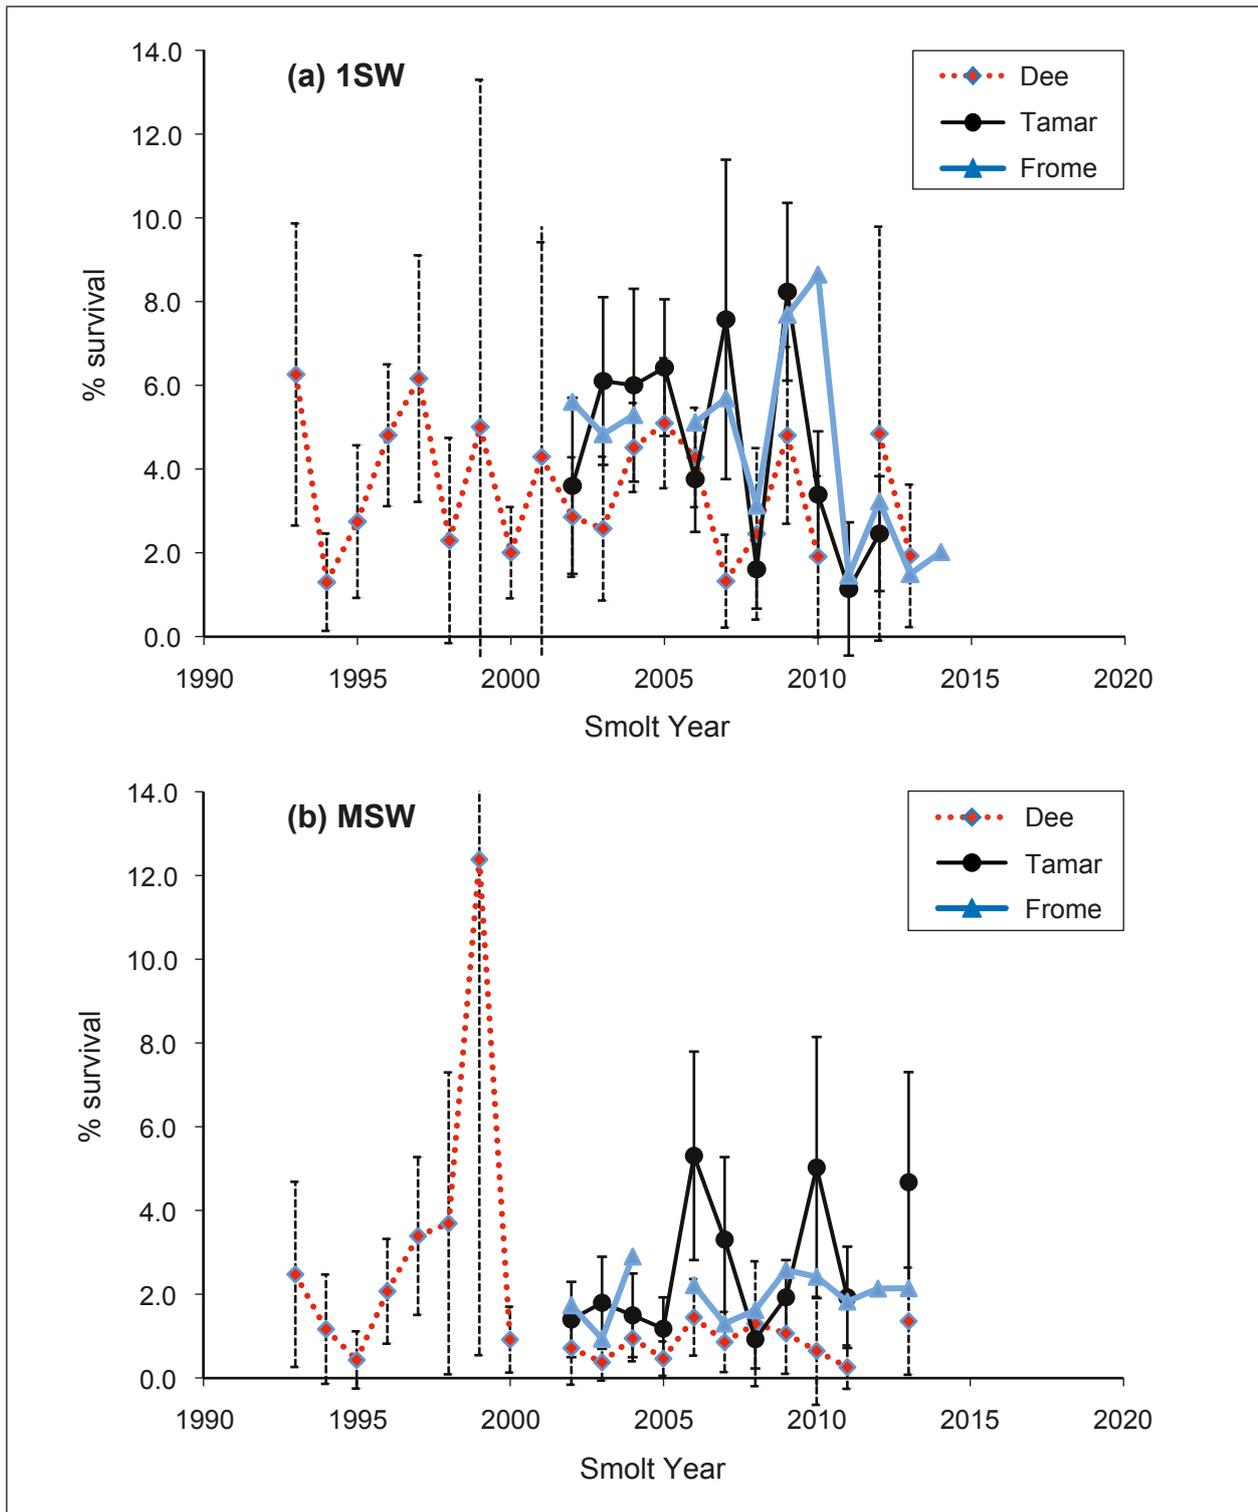

Figure 29. Estimated survival (\pm 95 CLs where available) of wild smolts (%) to return to homewaters (prior to coastal fisheries) for (a) 1SW and (b) MSW salmon for the Rivers Dee, Tamar and Frome.

8. ASSESSMENT OF STOCK STATUS

The status of individual river stocks in England and Wales is evaluated annually against stock conservation limits (CLs) and management targets (MTs) in line with the requirements of ICES and NASCO. A national assessment of the status of the salmon resource in England and Wales is also undertaken annually, using the Pre-fishery Abundance (PFA) and National Conservation Limit Models (Potter *et al.*, 2004), and reported to ICES to assist with the development of management advice for the distant water fisheries. Full details of these assessment approaches are provided in the background report.

Status of river stocks in 2015

Egg deposition estimates for 2015 have been calculated for each of the 64 main salmon rivers in England and Wales and values, expressed as the proportion of the CL attained, are provided in Table 26 and illustrated in Figure 30.

Twenty-two rivers (34%) were provisionally assessed as meeting their CL in 2015, an improvement on 2014 (13 rivers), which had been the lowest in the time series (Table 27). Twenty-one rivers (33%) were below 50% of their CL in 2015, compared with 28 rivers in 2014. There has been a downturn in levels of CL attainment in the last three years (Figure 31) following a period of relatively good CL attainment between 2004 and 2012 when levels of egg deposition were typically higher than those in the preceding decade. River-to-river variation in the proportion of the CL attained in 2015 (Figure 30) indicates that rivers where spawning escapement was below the CL were widely distributed throughout England and Wales.

In 2015, additional egg deposition resulting from fish that were caught and released is estimated at about 20 million eggs (assuming 80% survival to spawning, 50% females and an average of 5,000 eggs per female). This represents about 7% of the total estimated egg deposition in England and Wales in 2015.

Compliance with the management objective

The 'management objective' for salmon stocks in England and Wales is that they should meet or exceed their CLs in at least four years out of five, on average. Compliance with this objective takes trends in egg deposition into account, and has been calculated for all 64 principal river stocks in England and Wales for 2015 and forecast for 2020 (Table 26 and Figure 32).

The latest compliance assessment indicates that none of the principal rivers across England and Wales were classified as 'not at risk' in 2015 – having a high probability ($p > 95\%$) of achieving the management objective. The same is forecast to apply in 2020. In 2015, 23 rivers (36%) were classified as 'at risk' – having a low probability ($p < 5\%$) of achieving the management objective. Eleven rivers (17%) are forecast to be 'at risk' in 2020. Half of all rivers in England and Wales in 2015 (50%) are classified as 'probably at risk' ($5\% < p < 50\%$ of achieving the management objective); this rises to 63% in 2020. Nine rivers (14%) are classified as 'probably not at risk' ($50\% \leq p < 95\%$) in 2015, compared with just 4 rivers in 2014. The compliance figures are summarised, separately, for rivers in England and Wales below:

Rivers in England

Stock status category	Probability of meeting the management objective	2015		2020	
		Number of rivers	%	Number of rivers	%
Not at risk	>95%	0	0	0	0
Probably not at risk	50–95%	8	19	11	26
Probably at risk	5–50%	22	52	25	60
At risk	<5%	12	29	6	14

Rivers in Wales

Stock status category	Probability of meeting the management objective	2015		2020	
		Number of rivers	%	Number of rivers	%
Not at risk	>95%	0	0	0	0
Probably not at risk	50–95%	1	5	2	9
Probably at risk	5–50%	10	45	15	68
At risk	<5%	11	50	5	23

For rivers in England (Figure 33a) there has been a general decrease in the proportion of rivers regarded as 'at risk' over the past 12 years, and this is predicted to continue. However, while the percentage of rivers classified as 'not at risk' was relatively stable, at about 20%, over the early part of the time series, there has been a progressive decline in the rivers in this category in the last four years with none assessed as 'not at risk' in the last two years, and this is predicted to continue in 2020. There was an increase in the number of rivers classified as 'probably not at risk' in 2015 compared with 2014. However, the majority of rivers (55%) continue to fall in the 'probably at risk' category, as in 2014. The 2015 assessment suggests that the majority (74%) of English rivers will fall in the 'probably at risk' and 'at risk' categories in 2020.

For Wales (Figure 33b), a higher proportion of rivers have fallen in the 'at risk' category over the time series and very few rivers have been classed as 'not at risk'. In 2015, all the rivers except one are classified as either 'at risk' (50%) or 'probably at risk' (45%). The predicted trend suggests that 91% of rivers will fall in the same two categories in 2020, but with the majority classed as 'probably at risk'.

The latest assessment thus indicates that the majority of salmon stocks in England and Wales remain in a depleted state.

Assessment of pre-fishery abundance (PFA) for England and Wales

Each year, ICES makes an assessment of the status of the salmon stocks in the Northeast Atlantic (NEAC) area as a basis for advising managers and providing catch advice for the distant water fisheries. A key part of this assessment is the estimation of the pre-fishery abundance (PFA) of all NEAC stocks, which is defined as the number of fish alive in the sea on January 1 in their first sea winter. This is split between maturing (potential 1SW) and non-maturing (potential

MSW) fish. The PFA estimates for the period since 1971 provide our best interpretation of what the available catch and effort data tell us about changes in the status of the total national stock of salmon over the past four to five decades.

The estimated PFA of salmon from England and Wales has declined by approaching 50% from the early 1970s to the present time (Figure 34). Over much of the period, the decrease has tended to be somewhat greater for the non-maturing (i.e. potential MSW) component of the PFA than the maturing 1SW (i.e. potential grilse) component. However, there has been a marked reduction in the PFA of 1SW salmon in the last five years, and this difference is now less apparent. It should be noted that these trends mask conflicting changes in individual river stocks. Many rivers have experienced more serious declines but these are obscured by the very substantial improvements and recovery in others. The results also suggest that there was a marked decline in PFA around 1990, which is consistent with the general perception of a decrease in the marine survival for many stocks around the North Atlantic at about this time. [NB the model cannot provide an estimate of PFA of potential MSW fish for the most recent year, as this relies on an assessment of the returns to homewaters of these fish, which will not occur until the subsequent year].

The estimated numbers of salmon returning to rivers in England and Wales (prior to exploitation in homewater fisheries) are also derived from the ICES national assessment. These estimates show a similar downward trend to the PFA (Figure 35), although the decrease is less marked due to the reduction in net exploitation in distant water fisheries. Thus, numbers of returning fish are estimated to have declined by about 45% between the early 1970s and the present time. As with the PFA, the decline in returning MSW fish has tended to be greater than that of the 1SW (grilse) returns over much of the time period. However, a higher proportion of MSW fish has been observed in recent years and the percentage reduction in returning fish between the start and the end of the times series is now greater for 1SW fish.

The difference between the estimated numbers of returning fish and those surviving to spawn has reduced progressively over the time series and the total spawning escapement has remained reasonably consistent over the period (Figure 35). This reflects the marked reduction in levels of exploitation in homewater net and rod fisheries, including the increasing use of catch and release. The recent upturn in MSW returns means that MSW spawner numbers are now similar to those at the start of the time period. This will be expected to have a disproportionate effect on egg deposition, given the substantially higher fecundity of these larger fish.

Table 26. Conservation Limits (CL) and the percentage of the CL attained for the principal salmon rivers in England and Wales, 2006–2015. Current compliance against the management objective and predicted compliance in 2020 are also shown.

Key to compliance assessments: **NaR** Not at risk **PNaR** Probably not at risk **PaR** Probably at risk **AR** At risk

(a) Estimates include eggs contributed by rod-released fish.

(b) Basis for current and predicted compliance explained in Background Report (see text for details).

(c) Provisional salmon counts now used on the Tyne to estimate egg deposition.

(d) Prior to 1 April 2005, Border Esk egg deposition estimates were based only on English rod catch and likely to be underestimates.

Notes: Some entries in this table have been updated from that presented in previous reports as a result of river-specific refinements and corrections.

On some rivers, catch returns from fishery owners (rather than declared catches) or data from counters/traps have been used to derive estimates of egg deposition where these are considered to provide the most complete record of the returning stock.

Data for 2015 are provisional.

9. FACTORS AFFECTING STOCKS, FISHERIES AND CATCHES

9.1 *Management measures*

Viewed against historical data, current stock estimates and catches provide ongoing cause for concern and the conservation of salmon remains a priority. As a result, the Environment Agency hosted a Salmon Summit on 19 November 2015, to raise awareness about the state of England's salmon stocks and to bring together influential leaders, policy makers, delivery bodies and NGOs to discuss and agree how we can collectively protect and enhance them. The Environment Agency, Defra, its agencies and partner organisations are now developing a five-point approach to deliver a better future for salmon, which aims to address the pressures that they face through their life-cycle. This includes proposals for action on:

- Improving marine survival;
- Further reducing exploitation by nets and rods;
- Removing barriers to migration and enhancing habitat;
- Safeguarding sufficient flows; and
- Maximising spawning success by improving water quality.

Starting in April 2016, the Environment Agency is putting in place an 18-month programme to kick-start the new approach and help coordinate the actions to be undertaken by a range of organisations over the period 2016-2021.

A number of measures aimed at better management of this valuable resource have also been implemented or strengthened in England and Wales in recent years. The following provides a brief overview:

- The number of licences issued for nets and fixed engines in all parts of England and Wales has continued to decline as a result of measures taken to reduce levels of exploitation and the declining commercial viability of some fisheries. Overall, the number of net licences has decreased by 76% since 1971.
- The national spring salmon measures introduced in 1999 have reduced the proportion of the net catch taken before June from a 5-year average of 6.7% in the mid-1990's to 0.3%, on average, from 1999; these latter fish are all required to be released. These measures were renewed for another ten years in December 2008.
- Several net fisheries are being (or have been) phased out because they exploit migratory salmonids returning to more than one river (i.e. mixed stock fisheries). Arrangements have also been made to reduce netting effort in some fisheries by either compensating netsmen not to fish for a particular period (buy-offs), or through voluntary agreement to return salmon alive. Catch limits have also been imposed on some net and fixed engine fisheries.

- In Ireland, action by the Government and fisheries authorities in 2007 imposed new restrictions on their fisheries and ended legal coastal drift netting for salmon. This change is estimated to have resulted in up to 5,000 more grilse returning to homewaters, particularly to rivers in the south and west of England and Wales.
- The national spring salmon measures have also affected rod fisheries. The proportion of the rod catch taken before June fell from a mean of 10.9% over the period 1994–1998 to an average of 6.2% for the period since 1999, and these fish are now required to be released.
- Non-statutory restrictions on methods and fishing areas imposed by fishery owners and angling associations include weekly and seasonal bag limits, and there are ongoing efforts to promote catch and release (C&R). As a consequence, the proportion of salmon released by anglers has increased steadily from 10% in 1993 to at or above 60% in the last six years (79%, provisionally, in 2015, the highest in the time series). Tracking studies suggest that, if handled appropriately, the majority (~85%) of released salmon go on to spawn successfully.

9.2 Other factors

Other, non-regulatory, factors may also contribute to changes in stocks and catches, for example, the condition of returning fish, weather conditions, water quality, extreme flow events and the market prices of wild and farmed fish. Further information on these factors is provided in the background report. The following provides brief details of factors pertinent to 2015:

The effect of river flows on angler effort and catches

For rod fisheries, river flow is a key factor affecting angler effort. In 2015, river flows were generally a little below the long-term average for much of the fishing season, but with flows well below average in September and October (Figure 36). The early autumn represents an important period for most rod fisheries and relatively low flows at this time are likely to have affected runs of fish and provided conditions that were unfavourable for angling, particularly for 1SW salmon, since these only start to return to rivers in the summer months. This would likely also have had an effect on fishing effort at this time.

Monthly rod catch data for the majority of the rivers featured in Figure 36, expressed in the same format as the flow data, as a percentage of the long-term average, are presented in Figure 37. This excludes the River Cynon, which has no catch of salmon, and includes the catch for the whole River Tyne rather than just the South Tyne tributary. The long-term average for the rod data has only been extended back as far as 1999, which is when the national measures were introduced imposing compulsory catch and release in the early part of the season. Fishing patterns are likely to have been different prior to this time. The monthly rod catch data have also been restricted to the period February to October, since for most rivers fishing seasons do not extend outside this period.

Median monthly rod catches in 2015 were below the long-term average in February and March, above the long-term average for much of the spring and summer (April to August inclusive), but well below average again in September and October. The particularly low indications for February and March need to be treated with caution since there is relatively little fishing at this time of year, catches are very small and fishing is restricted to only some rivers. The above average catches,

in spring in particular, probably reflect the improved returns of MSW salmon, many of which return earlier in the year. The low flows in September and October will have resulted in relatively poor conditions for salmon angling and for fish to migrate, and will have contributed to the below average catches at this time. However, it is important to remember that differing proportions of 1SW and MSW fish in the runs and the timing of the return migrations will also have an impact on catch rates, in addition to river flows. The continued very low numbers of returning 1SW salmon (Figure 19) will thus also have contributed to the poor late season catches. Overall, conditions for salmon angling in 2015 appear to have been relatively poor with rod catches remaining among the lowest in the time series (Figure 11).

Particularly severe floods occurred towards the end of 2015 in a number of regions in England and Wales (Figure 36). This occurred after the close of the fishing season in most places, so would not have impacted on angling. However, the high flows are expected to have coincided with the salmon spawning period; it is currently unclear what effect this may have had on spawning success or on resulting fry and parr densities.

First sale price of salmon

The first sale price of salmon has potential implications for fishing effort and the economic viability of those net fisheries that target these fish. The average monthly price of wild salmon varies seasonally, reflecting both availability and the size of fish. Figure 38 provides an indication of trends in the first sale price of both wild and farmed salmon since 1978. The data (from Mawle, in prep) are provided for a single month, August. Further discussion on these price changes is provided in the background report.

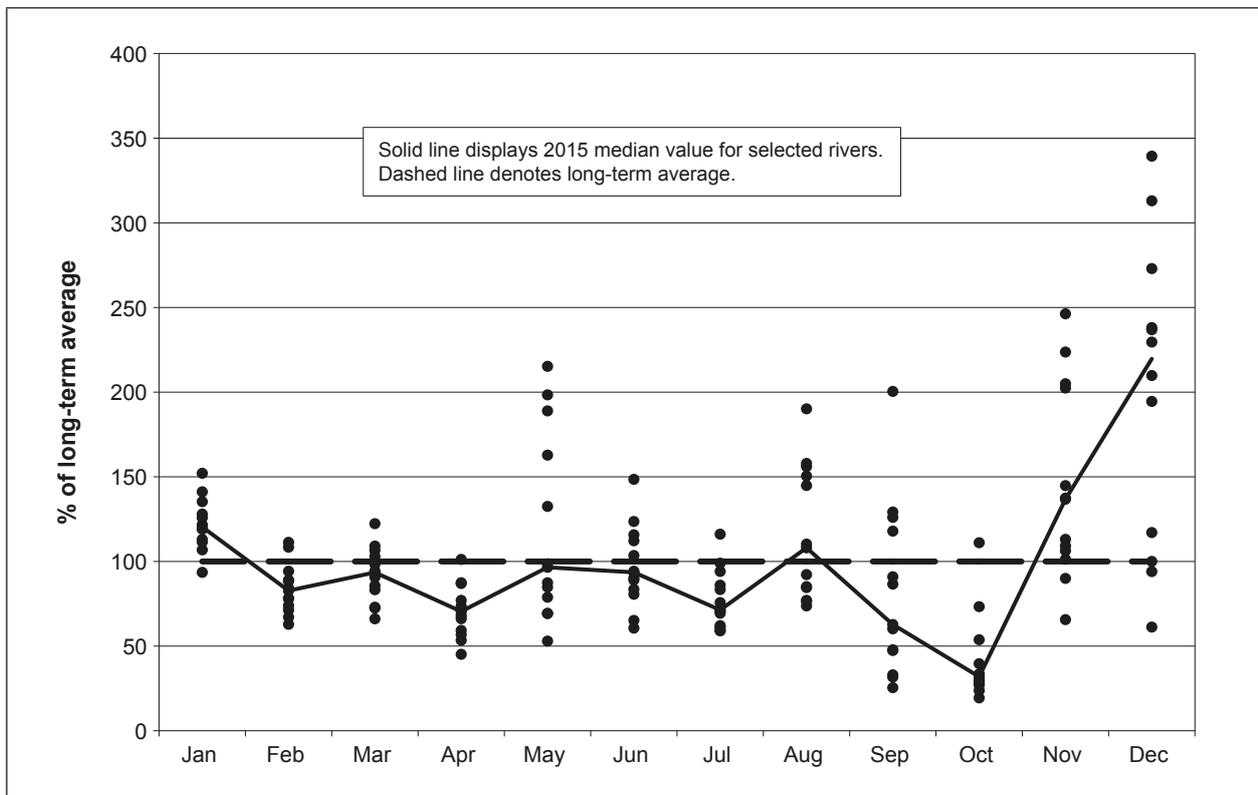

Figure 36. Monthly mean river flows (cubic metres per second) in 2015 for 12 rivers (South Tyne, Itchen, Avon, Exe, Taw, Severn, Wye, Cynon, Teifi, Dee, Lune and Eden) in England & Wales, expressed as a percentage of the long-term average on each river for the same month. (Data supplied courtesy of the National River Flow Archive at the Centre for Ecology and Hydrology.)

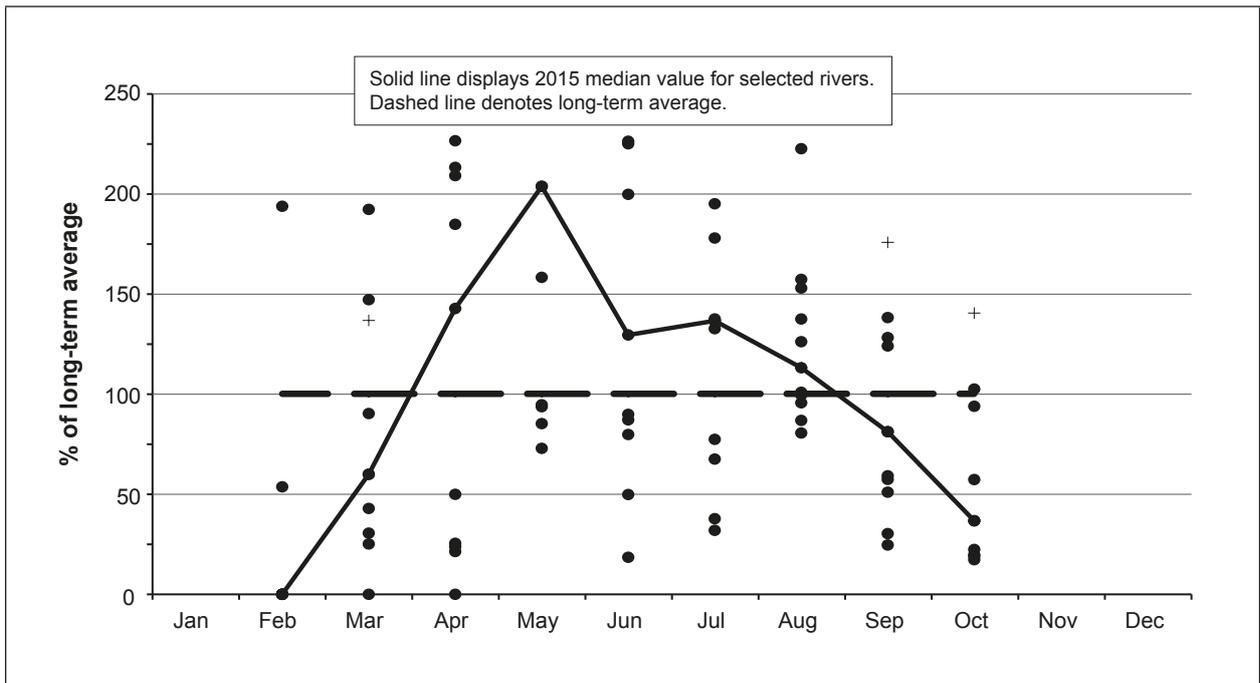

Figure 37. Monthly rod catches in 2015 for 11 rivers (Tyne, Itchen, Avon, Exe, Taw, Severn, Wye, Teifi, Dee, Lune and Eden) in England & Wales, expressed as a percentage of the long-term average on each river for the same month.

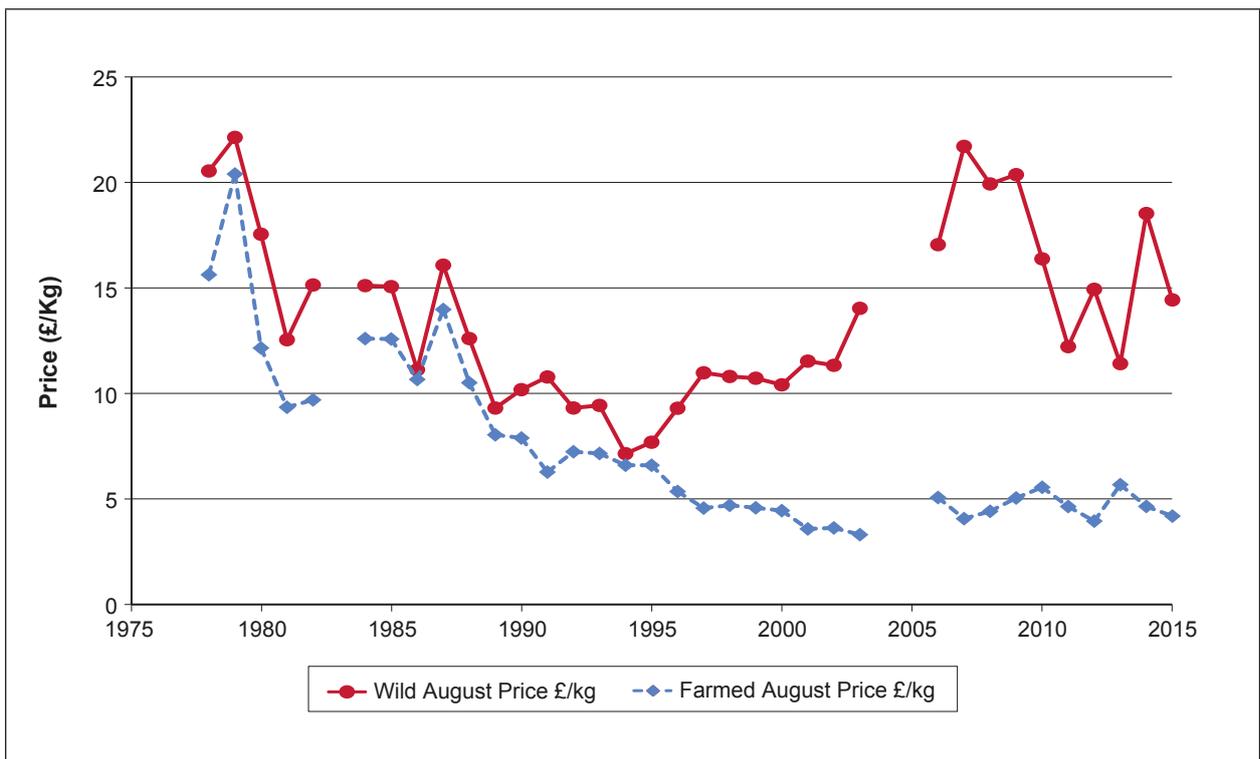

Figure 38. The average price of farmed salmon and wild Scottish salmon sold in August at Billingsgate, London, 1978 to 2015.

10. EXISTING AND EMERGING THREATS TO SALMON POPULATIONS

Further information on the various factors impacting on salmon stocks in England and Wales is reported in the NASCO Implementation Plan and in the annual progress reports to NASCO. These reports are available at: http://www.nasco.int/implementation_plans_cycle2.html. Some additional information is also available in the background report. The following provides a brief update on one issue:

Red Vent Syndrome and other disease issues

The occurrence of salmon returning to rivers in England and Wales with swollen and/or bleeding vents has been noted since 2004. The condition, referred to as Red Vent Syndrome (RVS), has continued to be observed since this time, and has been subject to ongoing monitoring. Monitoring programmes on salmon 'index' rivers provide the most consistent measure of the incidence of RVS. Since 2007, this consistency has been improved through the introduction of a system whereby symptoms have been classified according to their apparent severity (with samplers referring to a set of standard photographs and descriptions to assist their judgement). Time series of RVS incidence in returning fish are presented in Table 28 for the Rivers Tyne, Tamar, Dee, Lune and Caldew (a tributary of the River Eden). However, no sampling has been possible at two of these sites in the last two years and sampling effort has been substantially reduced at another.

Fish affected by RVS show a degree of recovery in freshwater and appear to be able to spawn successfully.

The Environment Agency and Natural Resources Wales also maintain a watching brief regarding other possible diseases on all major salmon rivers. For example, in some recent years, a number of reports have been received of Atlantic salmon and sea trout showing signs of fungal infections. In 2015, particular concerns about the prevalence of such fish on the River Dart, together with wider concerns about stock status, led to the implementation of an emergency byelaw in mid-July. This required the seine net fishery to release all salmon and for this fishery to close early. Rod anglers were also required to practice 100% C&R and spinning was also banned to reduce stress on released fish.

Table 28. Percentage of returning salmon showing signs of Red Vent Syndrome in monitored rivers in England and Wales, 2004–2015.

River	Tyne #	Tamar	Dee	Lune	Caldew #
Region/NRW	NE	SW	N. Wales	NW	NW
Sample source	Upper river broodstock	Lower river trap	Lower river trap	Lower river trap	Sub-catchment trap
% incidence of RVS in returning fish					
2004			0.4		
2005			3.2	0	
2006			9.2	1.4	
2007	1.4	60.2	29.9	23.1	5.3 ^[a]
2008	0.8	45.3	20.9	24.7	0.3 ^[a]
2009	3.4	41.5	28.2	21.2	10.2
2010	5.3	57.1	23.7	18.8	5.1
2011	3.8	45.6	10.9	16.3	6.4
2012	5.2	26.1	13.2	0 ^[a]	6.1
2013	10.1	44.5 #	20.5	41.6	0.8 ^[a]
2014	7.5	n/a	25.3	9.5 #	n/a
2015	10.3	n/a	24.4	13.6 #	n/a

Note: Except where indicated (#), these estimates are based on fish sampled over a common (June–October) period and have been weighted according to monthly run totals. Three of the traps (not the Caldew) are located at or close to head-of-tide.
^[a] Minimum values.

ANNEX 1. NASCO's request for scientific advice from ICES in 2016

1. With respect to Atlantic salmon in the North Atlantic area:

- 1.1 provide an overview of salmon catches and landings by country, including unreported catches and catch and release, and production of farmed and ranched Atlantic salmon in 2015¹;
- 1.2 report on significant new or emerging threats to, or opportunities for, salmon conservation and management²;
- 1.3 provide a review of examples of successes and failures in wild salmon restoration and rehabilitation and develop a classification of activities which could be recommended under various conditions or threats to the persistence of populations³;
- 1.4 advise on possible effects of salmonid aquaculture on wild Atlantic salmon populations focusing on the effects of sea lice, genetic interactions and the impact on wild salmon production⁴;
- 1.5 provide a time series of numbers of river stocks with established CLs and trends in numbers of stocks meeting their CLs by jurisdiction;
- 1.6 provide a compilation of tag releases by country in 2015;
- 1.7 identify relevant data deficiencies, monitoring needs and research requirements.

2. With respect to Atlantic salmon in the North-East Atlantic Commission area:

- 2.1 describe the key events of the 2015 fisheries⁵;
- 2.2 review and report on the development of age-specific stock conservation limits;
- 2.3 describe the status of the stocks;
- 2.4 advise on the source of uncertainties and possible biases in the assessment of catch options for the Faroes fishery resulting from the use of samples and data collected in the fishery in the 1980s and 90s. Should it be considered that biases are likely to compromise the catch advice, advise on any new sampling which would be required to improve these assessments;

*In the event that NASCO informs ICES that the Framework of Indicators (FWI) indicates that reassessment is required:**

- 2.5 provide catch options or alternative management advice for 2016/17-2018/19 fishing seasons, with an assessment of risks relative to the objective of exceeding stock conservation limits, or pre-defined NASCO Management Objectives, and advise on the implications of these options for stock rebuilding⁶; and
- 2.6 update the Framework of Indicators used to identify any significant change in the previously provided multi-annual management advice.

3. With respect to Atlantic salmon in the North American Commission area:

- 3.1 describe the key events of the 2015 fisheries (including the fishery at St Pierre and Miquelon)⁵;
- 3.2 update age-specific stock conservation limits based on new information as available;

3.3 describe the status of the stocks;

*In the event that NASCO informs ICES that the Framework of Indicators (FWI) indicates that reassessment is required:**

3.4 provide catch options or alternative management advice for 2016-2019 with an assessment of risks relative to the objective of exceeding stock conservation limits, or pre-defined NASCO Management Objectives, and advise on the implications of these options for stock rebuilding⁶;

3.5 update the Framework of Indicators used to identify any significant change in the previously provided multi-annual management advice.

4. With respect to Atlantic salmon in the West Greenland Commission area:

4.1 describe the key events of the 2015 fisheries⁵;

4.2 describe the status of the stocks⁷;

4.3 compare contemporary indices of abundance of salmon in the West Greenland fishery to historical estimates and suggest options for improving future estimates;

4.4 estimate the effects of modifying the timing of the West Greenland salmon fishery, including altering the start date, with regard to harvest and exploitation of contributing stocks;

4.5 advise on changes to temporal and/or spatial fishery patterns that may provide increased protection for weaker stocks;

*In the event that NASCO informs ICES that the Framework of Indicators (FWI) indicates that reassessment is required:**

4.6 provide catch options or alternative management advice for 2016-2019 with an assessment of risk relative to the objective of exceeding stock conservation limits, or pre-defined NASCO Management Objectives, and advise on the implications of these options for stock rebuilding⁶; and

4.7 update the Framework of Indicators used to identify any significant change in the previously provided multi-annual management advice.

Notes:

1. *With regard to question 1.1, for the estimates of unreported catch the information provided should, where possible, indicate the location of the unreported catch in the following categories: in-river; estuarine; and coastal. Numbers of salmon caught and released in recreational fisheries should be provided.*
2. *With regard to question 1.2, ICES is requested to include reports on any significant advances in understanding of the biology of Atlantic salmon that is pertinent to NASCO, including information on any new research into the migration and distribution of salmon at sea and the potential implications of climate change for salmon management.*
3. *With regards to question 1.3, NASCO is particularly interested in case studies highlighting successes and failures of various restoration efforts employed across the North Atlantic by all Parties/jurisdictions and the metrics used for evaluating success or failure.*

4. *In response to question 1.4, ICES is requested to review and update the findings of the ICES/NASCO symposium on the impacts of aquaculture and the request for advice from OSPAR in June 2010.*
5. *In the responses to questions 2.1, 3.1 and 4.1, ICES is asked to provide details of catch, gear, effort, composition and origin of the catch and rates of exploitation. For homewater fisheries, the information provided should indicate the location of the catch in the following categories: in-river; estuarine; and coastal. Information on any other sources of fishing mortality for salmon is also requested.*
6. *In response to questions 2.5, 3.4 and 4.6, provide a detailed explanation and critical examination of any changes to the models used to provide catch advice and report on any developments in relation to incorporating environmental variables in these models.*
7. *In response to question 4.2, ICES is requested to provide a brief summary of the status of North American and North-East Atlantic salmon stocks. The detailed information on the status of these stocks should be provided in response to questions 2.3 and 3.3.*

*** The aim should be for NASCO to inform ICES by 31 January of the outcome of utilising the FWI.**

ANNEX 2. Net Limitation Orders applying to salmon net fisheries in England & Wales

EA Region / NRW	Area	Net Limitation Order	End date	Welsh rivers in Wales 'all areas' NLO	NLO licence provision

	Derwent	1.2 -31.10			
	Ellen	1.2 -31.10			
	Eden	15.1 -14.10		Byelaw (NW-13.11.07) no more than two salmon may be killed between 16.6 and 14.10	13.11.2007 – 12.11.2017
				Byelaw (NW-13.11.07) prohibits retention of female salmon 10.9 to 14.10	13.11.2007 – 12.11.2017
	Esk (Border)	1.2 -31.10		Byelaw (NW-13.11.07) no more than two salmon may be killed between 16.6 and 31.10	13.11.2007 – 12.11.2017
				Byelaw (NW-13.11.07) prohibits retention of female salmon 10.9 to 31.10	13.11.2007 – 12.11.2017
	Others	1.2 -31.10 (b)			

Notes:

(a) Season 3.3 to 25.10 Rivers Irfon, Ithon and main River Wye upstream of Llanwrthwl Bridge

(b) Applies to all other watercourses in the North West not named specifically above.

* National spring salmon byelaws apply.

Natural Resources Wales – variations apply to Anglesey and the Lleyn Peninsula (check local byelaws).

Always check local byelaws before fishing.
